1. **Introduction and terminology.** Suppose that

$$(1.1) \quad f(z) = \sum_0^{\infty} a_n z^n = u + iv$$

is a transcendental integral function. In this article we develop the theory initiated

Received by the editors April, 1972

by Wiman [22, 23] and deepened by other writers including Valiron [18, 19, 20], Saxer [15], Clunie [4, 5] and Kövari [10, 11], which describes the local behaviour of $f(z)$, near a point where $|f(z)|$ is large, in terms of the power series† of $f(z)$. The theory leads in particular to a good account of the relation between the maximum modulus

$$(1.2) \quad M(r, f) = \sup_{|z|=r} |f(z)|,$$

and the maximum term

$$(1.3) \quad \mu(r) = \sup_n |a_n| r^n = a_N r^N$$

say. Here $N=N(r)$ is called the *central index*. If there are several maximum terms, which can only happen for isolated values of r we define $N(r)$ to be the largest of the corresponding indices. The theory also allows us to compare

$$(1.4) \quad A(r) = \inf_{|z|=r} u(z) \quad \text{and} \quad B(r) = \sup_{|z|=r} u(z)$$

with $M(r)$.

We recall that $\log M(r)$ is an increasing convex function of $\log r$. Thus

$$(1.5) \quad a(r) = r \frac{d}{dr} \log M(r), \quad \text{and} \quad b(r) = r \frac{d}{dr} a(r)$$

exist except for isolated values of r and $a(r)$ increases with r , while $b(r) \geq 0$.

We note that $N(r)$ is an increasing function of r and $N(r) \rightarrow \infty$ with r . If

$$(1.6) \quad N(r) = N \quad \text{for} \quad r_N \leq r < r_{N+1}$$

we see that

$$(1.7) \quad r \frac{d}{dr} \log \mu(r) = N = N(r), \quad r_N < r < r_{N+1}.$$

Since $\mu(r)$ is continuous at the points r_N , we deduce that

$$(1.8) \quad \log \mu(r) = \log \mu(r_0) + \int_{r_0}^r \frac{N(t) dt}{t}, \quad 0 < r_0 < r < \infty.$$

Thus $\log \mu(r)$ is also a convex increasing function of $\log r$.

1.1. Densities. In order to develop our results we shall need various kinds of measures and densities for sets of points on the positive axis. Let E be such a set and let $E[a, b]$ denote the part of E for which $a < r < b$. The linear and logarithmic measures of E are defined to be

$$m(E) = \int_E dr \quad \text{and} \quad lm(E) = \int_{E(1, \infty)} \frac{dr}{r}$$

respectively. These may be finite or infinite. We also define the lower and upper

† For an extension of the theory to functions in a finite disk see [12].

densities of E by

$$\overline{\text{dens}} E = \overline{\lim}_{r \rightarrow \infty} \frac{m(E(0, r))}{r}$$

and the upper and lower logarithmic densities of E by

$$\overline{\log \text{dens}} E = \overline{\lim}_{r \rightarrow \infty} \frac{lm(E(1, r))}{\log r}.$$

The definition (1.3) only tells us that the term with index N equal to the central index is larger than any of the others in the power series (1.1). The key result of the Wiman–Valiron Theory allows us to obtain a definite inequality for

$$\frac{|a_n| r^n}{\mu(r)}$$

when n is unequal to N , which is valid for all n and ‘most’ values of r in a certain sense and shows that the terms for which $|n - N| \geq k$ are negligible compared with $\mu(r)$ if for instance $k \geq N^{1/2+\delta}$. This reduces the local behaviour of $f(z)$ essentially to that of $z^{N-k}P(z)$, where $P(z)$ is a polynomial of degree at most $2k$.

1.2. **The basic results.** We now introduce the comparison series. Let $\alpha_n, n=0$ to ∞ be a sequence of positive numbers such that α_{n+1}/α_n decreases with increasing n . Let ρ_n be a sequence of numbers such that

$$(1.9) \quad 0 < \rho_0 < \frac{\alpha_0}{\alpha_1}, \quad \frac{\alpha_{n-1}}{\alpha_n} < \rho_n < \frac{\alpha_n}{\alpha_{n+1}}, \quad n \geq 1$$

so that ρ_n increases with increasing n . We shall say that a value r is *normal* (for the sequences a_n, ρ_n and α_n) if we have for some N

$$(1.10) \quad |a_n| r^n \leq |a_N| r^N \frac{\alpha_n \rho_N^n}{\alpha_N \rho_N^N}, \quad n = 0 \text{ to } \infty.$$

It follows from the definition of ρ_N that for $n \neq N$

$$(1.11) \quad \frac{\alpha_n}{\alpha_N} < \rho_N^{N-n},$$

so that if (1.10) holds, $N=N(r)$ is necessarily the central index of $f(z)$. It turns out that, the more rapidly α_n tends to zero, the stronger on the whole is the information contained in (1.10), but the smaller is the set of normal r . The set of r which are not normal will be called *exceptional*.

The following result gives us information about the size of the set of normal r in different situations.

THEOREM 1. *Suppose that r_N is defined by (1.6) and that ρ_N satisfies (1.9). Then*

- (i) *If ρ_N is bounded above the set of exceptional r has finite logarithmic measure;*

(ii) if

$$\overline{\lim}_{N \rightarrow \infty} \frac{\log \rho_{N+1}}{\log r_N} = \delta < 1$$

then the set of exceptional r has upper logarithmic density at most δ .

(iii) If $\rho_N/r_N \rightarrow 0$ as $N \rightarrow \infty$, the set of normal r has infinite logarithmic measure.

If $N(r)$ jumps from N to $N+k$ as r increases through the value r_{N+1} , we define $r_{N+1} = r_{N+2} = \dots = r_{N+k}$. With this definition we see that

$$|a_{N+k}| r_{N+k}^{N+k} = |a_N| r_{N+1}^N$$

so that

$$|a_{N+k}| = \frac{|a_N|}{r_{N+1}^k} = \frac{a_N}{r_{N+1} \cdots r_{N+k}},$$

and

$$|a_{N+v}| \leq \frac{|a_N|}{r_{N+1}^v}, \quad 1 \leq v \leq k.$$

Thus we always have

$$\frac{|a_N|}{|a_0|} \leq \frac{1}{r_1 r_2 \cdots r_N}.$$

On the other hand we deduce from (1.9) that

$$\frac{\alpha_n}{\alpha_{n-1}} \geq \frac{1}{\rho_n},$$

so that

$$\frac{\alpha_N}{\alpha_0} \geq \frac{1}{\rho_1 \rho_2 \cdots \rho_N}.$$

In particular

$$\left(\frac{a_N}{\alpha_N} \right)^{1/N} \leq \left(\frac{a_0 \rho_1 \cdots \rho_N}{\alpha_0 r_1 r_N} \right)^{1/N} \rightarrow 0 \quad \text{as } N \rightarrow \infty$$

even under the weakest hypothesis (iii) of Theorem 1. Thus if any of the hypotheses (i), (ii) or (iii) of that theorem hold, and we set

$$A_N = \left| \frac{a_N}{\alpha_N} \right|,$$

it follows that

$$F(z) = \sum_0^{\infty} A_n z^n$$

is an integral function. It follows that for $0 < \rho < \infty$, $F(z)$ has a maximum term for $|z| = \rho$, and if $M = M(\rho)$ is the central index of $F(z)$ for $|z| = \rho$, we deduce that

$$A_n \rho^n \leq A_M \rho^M, \quad n = 0 \text{ to } \infty.$$

The inequality can be written as

$$(1.12) \quad \frac{|a_n| (\rho \rho_M)^n}{|a_M| (\rho \rho_M)^M} \leq \frac{\alpha_n \rho_M^n}{\alpha_M \rho_M^M} < 1, \quad n \neq N$$

in view of (1.11). Thus if we set $r = \rho \rho_M$, it follows that $N(r) = M$, and the inequality (1.10) holds. Thus r is *normal* if r takes this form, i.e. if we can write $r = \rho \rho_M$, where M is the central index of $F(z)$ for $|z| = \rho$.

Let (R_n, R_{n+1}) be the interval in which the central index of $F(z)$ is n , so that R_n is defined for $F(z)$ as r_n is defined for $f(z)$ by (1.6). Then the intervals $(R_n \rho_n, R_{n+1} \rho_n)$ are normal so that the exceptional values of r are contained in the complementary intervals of the form $(R_n \rho_{n-1}, R_n \rho_n)$. Let E_N be the set of these complementary intervals for $n = 1$ to N . Then

$$lm(E_N) \leq \sum_{n=1}^N \int_{R_n \rho_{n-1}}^{R_n \rho_n} \frac{dt}{t} = \log \frac{\rho_N}{\rho_0}.$$

Also the exceptional r for $r \leq R_{N+1} \rho_N$ are contained in E_N .

Next we recall that the central index of $f(z)$ is n in the interval $(\rho_n R_n, \rho_n R_{n+1})$, so that $r_n \leq \rho_n R_n$. Thus if $r_n \leq r \leq r_{n+1}$, we deduce that $r \leq \rho_{n+1} R_{n+2}$, so that the exceptional t in $(0, r)$ are contained in E_{n+1} and so have logarithmic measure at most $\log(\rho_{n+1}/\rho_0)$. Thus if E is the set of exceptional t , we have

$$lm(E(1, r)) \leq \log \frac{\rho_{n+1}}{\rho_0}, \quad r_n \leq r \leq r_{n+1}.$$

Now Theorem 1 follows at once. If ρ_N is bounded above then so is $lm(E(1, r))$ as $r \rightarrow \infty$, so that E has finite logarithmic measure. If (ii) holds then

$$\frac{lm(E(1, r))}{\log r} \leq \frac{\log \rho_{n+1} + O(1)}{\log r} \leq \frac{\log \rho_{n+1} + O(1)}{\log r_n} \leq \delta + o(1), \quad \text{as } n \rightarrow \infty,$$

so that our conclusion follows again. Finally if (iii) holds then

$$lm(E(1, r_{n+1})) \leq \log \rho_{n+1} + O(1),$$

so that if E' is the set of normal r , we have

$$lm(E'(1, r_{n+1})) \geq \log \frac{r_{n+1}}{\rho_{n+1}} + O(1) \rightarrow \infty, \quad \text{as } n \rightarrow \infty.$$

Thus in this case E' must have infinite logarithmic measure. This completes the proof of Theorem 1.

2. Construction of the comparison sequences. We now proceed to give a general method due to Kövari [11], for constructing the sequences α_n , which makes it easy to estimate the quantities occurring on the right hand side of (1.10). Such estimates are fundamental to the Wiman-Valiron method.

Suppose then that $\alpha(t) \in C^1[0, \infty)$ and that $\alpha'(r) < 0$ there. We set

$$(2.1) \quad \alpha_n = K \exp\left\{\int_0^n \alpha(t) dt\right\}, \quad \rho_n = \exp\{-\alpha(n)\},$$

where K is a positive constant. Then for $n \geq 1$

$$\log \frac{\alpha_n}{\alpha_{n-1}} = \int_{n-1}^n \alpha(t) dt > \alpha_n = \log \frac{1}{\rho_n} > \int_n^{n+1} \alpha(t) dt = \log \frac{\alpha_{n+1}}{\alpha_n},$$

and the right hand inequality remains valid for $n=0$. This proves (1.9). Again

$$\begin{aligned} \frac{\alpha_n}{\alpha_M} \rho_M^{n-M} &= \exp\left\{\int_M^n (\alpha(t) - \alpha(M)) dt\right\} \\ &= \exp\left\{\int_M^n (n-t)\alpha'(t) dt\right\}. \end{aligned}$$

Thus we deduce that for $|n - M| \geq k$, we have

$$(2.2) \quad \frac{\alpha_n}{\alpha_M} \rho_M^{n-M} \leq \exp\left\{-\frac{1}{2}k^2 \alpha_{M,k}\right\},$$

where

$$(2.3) \quad \alpha_{M,k} = \min_{|M-t| \leq k} |\alpha'(t)|.$$

2.1. Estimates for the terms of integral functions. By specialising the function $\alpha(t)$ we can obtain a number of results adapted to particular situations.

THEOREM 2. *If $f(z)$ is any integral function we have for normal r and $n = k + N$, where $N = N(r)$ is the central index of $f(z)$,*

$$(2.4) \quad \frac{|a_n| r^n}{\mu(r)} \leq \exp\left\{-\frac{1}{2}b(|k| + N)k^2\right\},$$

where $\dagger b(N)^{-1} = KN \log N \cdots \log_i N (\log_{i+1} N)^{1+\delta}$, $K > 0$, $\log_i x$ iterated denotes the i times iterated logarithm, $\delta > 0$ and the set of exceptional r has finite logarithmic measure.

If we have some more information about the size of $f(z)$ we can obtain (2.4) with a larger value of $b(|k| + N)$. We give two further examples.

THEOREM 3. *Suppose that $f(z)$ has finite order ρ . Then for $c < 1/\rho$ (2.4) holds with $b(N) = c/N$. The corresponding set of exceptional r has upper logarithmic density at most $c\rho$.*

\dagger This function is not to be confused with that defined by (1.5). If $b(r)$ is defined by (1.5) this will always be stated explicitly. Somewhat more general test functions were used by Kövari [11].

THEOREM 4. Suppose that for some constants $p \geq 2$ and $c > 0$, we have

$$\overline{\lim}_{r \rightarrow \infty} \frac{\log M(r, f)}{(\log r)^p} \leq c,$$

and take σ so that $\delta = \sigma(cpe)^{1/(p-1)} < 1$. Then for normal r we have (2.4) with $b(N) = \sigma(p-1)^{-1} N^{(2-p)/(p-1)}$ and the set of exceptional r has upper logarithmic density at most δ .

A corresponding result for $p < 2$ can be deduced but turns out to be less useful. The above results can all be deduced from (2.1) and (2.2) with a suitable choice of the function $\alpha(t)$. For Theorem 2 we take

$$\alpha'(t) = - \frac{1}{Kt \log t \cdots \log_t t (\log_{t+1} t)^{1+\delta}}, \quad t \geq t_0$$

$$\alpha'(t) = \alpha'(t_0), \quad t \leq t_0,$$

where t_0 is a sufficiently large positive number and set

$$\alpha(t) = \int_0^t \alpha'(\tau) d\tau.$$

Then $\alpha(t)$ is negative decreasing and bounded below as $t \rightarrow \infty$. Thus we can apply Theorem 1 and note that the exceptional set of r has finite logarithmic measure. Also $|\alpha'(t)|$ decreases with t , so that

$$\alpha_{M,k} = \min_{|M-t| \leq k} |\alpha'(t)| = -\alpha'(M+|k|).$$

Now (2.4) follows from (1.10), (2.2) and (2.3).

Next in the case of Theorem 3, we choose

$$\alpha'(t) = \frac{-c}{t}, \quad t \geq 1,$$

$$\alpha'(t) = -c, \quad t \leq 1,$$

so that $\alpha(t) = -c \log t, t \geq 1$, and then (2.1) with a suitable K gives

$$\rho_n = n^c, \quad \alpha_n = \exp\left\{-c \int_0^n \log t dt\right\} = (e/n)^{cn}, \quad n \geq 1.$$

Also by our hypotheses we have for $\rho_1 > \rho$

$$\log M(r, f) < \left(\frac{r}{e}\right)^{\rho_1}, \quad r > r_0$$

and so we have by (1.8),

$$\begin{aligned} N(r) &\leq \int_r^{er} \frac{N(t) dt}{t} \leq \log \mu(er) \\ &\leq \log M(er) < r^{\rho_1}, \quad r > r_0, \end{aligned}$$

so that $r_N \geq N^{1/\rho_1}$. This gives for all sufficiently large N

$$\frac{\log \rho_{n+1}}{\log r_n} \leq c\rho_1 \frac{\log(n+1)}{\log n},$$

and since ρ_1 may be chosen as near ρ as we please, we may apply Theorem 1 case (ii) with $\delta = c\rho$. Thus the set of exceptional r has upper logarithmic density at most $c\rho$.

We now note that $|\alpha'(t)|$ decreases for $t \geq 0$ so that we have

$$\alpha_{M,k} \geq |\alpha'(M+|k|)| = c/(M+|k|).$$

Now Theorem 3 follows from (1.10), (2.2) and (2.3).

Finally we suppose that $f(z)$ satisfies the hypotheses of Theorem 4. We set $k = 1 + p^{-1}$, and deduce that for $c' > c$ and r large, we have,

$$\begin{aligned} (k-1)N(r)\log r &\leq \int_r^{r^k} N(t) \frac{dt}{t} \leq \log \mu(r^k) \\ &\leq \log M(r^k) < c'k^p(\log r)^p. \end{aligned}$$

Thus

$$N(r) < c'p(1+p^{-1})^p(\log r)^{p-1} < cep(\log r)^{p-1}$$

if c' is sufficiently near c . Thus

$$r_N > \exp(N/cpe)^{1/(p-1)}.$$

We now assume that $\sigma(cpe)^{1/(p-1)} = \delta < 1$, and set

$$\alpha(t) = -\sigma t^{1/(p-1)},$$

so that (2.1) gives

$$\log \rho_N = \sigma N^{1/(p-1)},$$

and we deduce that

$$\overline{\lim}_{N \rightarrow \infty} \frac{\log \rho_{N+1}}{\log r_N} \leq \sigma(cpe)^{1/(p-1)} = \delta.$$

We can then apply (2.2) with (2.3). Also, since $p \geq 2$, $|\alpha'(t)|$ decreases with increasing p , and so we have again

$$\alpha_{M,k} = |\alpha'(M+|k|)|,$$

and we deduce Theorem 4.

3. The truncated series. We proceed to show that for normal $|z|$ and large $|f(z)|$ only a few terms in the neighbourhood of the maximum term are of genuine significance in the power series development of $f(z)$. We need first a general lemma on the growth of increasing functions.

LEMMA 1. *Suppose that $N(r)$ is a positive increasing function of r for $r \geq r_0$. Then if $\alpha > 0$, and $|h| < N(r)^{-\alpha}$, we have*

$$(3.1) \quad |N(re^h) - N(r)| < \alpha N(r)$$

for all r outside a set of finite logarithmic measure.

We shall assume that $N(r)$ is continuous on the right. For otherwise we may achieve this by altering $N(r)$ at a countable set of r and this will not affect the truth of (3.1) at other points.

For each $r \geq r_0$, we define $h(r) = N(r)^{-\alpha}$. We then define sequences r_n, r'_n inductively as follows. Let r_0 be the quantity of Lemma 1. If r_n has already been defined we define

$$r'_n = r_n \exp h(r_n), \quad r''_n = r'_n \exp h(r_n),$$

and r_{n+1} to be the least number † (if any) such that $r_{n+1} \geq r'_n$ and

$$N\{r_{n+1} \exp h(r_{n+1})\} \geq (1 + \alpha)N(r_{n+1}).$$

Evidently we have for $n \geq 1$, if r'_n is defined,

$$N(r'_n) \geq (1 + \alpha) N(r_n) \geq (1 + \alpha) N(r'_{n-1}) \geq \dots \geq (1 + \alpha)^n N(r_0).$$

Thus

$$\begin{aligned} \sum_1^\infty \log \left(\frac{r''_n}{r_n} \right) &= 2 \sum_1^\infty h(r_n) = 2 \sum_1^\infty N(r_n)^{-\alpha} \\ &\leq 2 \sum_1^\infty (1 + \alpha)^{-\alpha(n-1)} N(r_0)^{-\alpha} < \infty, \end{aligned}$$

so that the union E_0 of all the intervals $[r_n, r''_n]$ has finite logarithmic measure.

Let E_1 be the complement of E_0 in (r_0, ∞) and suppose that $r \in E_1$. Then either r_n is undefined for large n , in which case we have for all sufficiently large r

$$(3.2) \quad N\{r \exp h(r)\} < (1 + \alpha)N(r);$$

also if $r' = r \exp h(r)$, we have

$$r' \exp -h(r') \geq r' \exp -h(r) = r,$$

so that for all large r' we have

$$N\{r' \exp -h(r')\} \geq N(r) \geq \frac{1}{1 + \alpha} N(r') \geq (1 - \alpha)N(r').$$

Thus in this case (3.1) holds for all sufficiently large r .

Alternatively suppose that r_n is defined for all n , and let r be a point of E_1 . Then we have $r'_n < r < r_{n+1}$ for some n , so that (3.2) holds. Also suppose that

$$(3.3) \quad N(re^{-h(r)}) \leq (1 - \alpha)N(r).$$

Then if $\rho = r \exp (-h(r))$, we have

$$\rho e^{h(\rho)} \geq \rho e^{h(r)} = r,$$

so that

$$N(\rho e^{h(\rho)}) \geq \frac{1}{1 - \alpha} N(\rho) > (1 + \alpha)N(\rho).$$

† The fact that the lower bound is attained follows from the continuity on the right of $N(r)$.

Thus ρ must lie in one of the intervals $[r_v, r'_v]$ and so

$$r = \rho e^{h(r)} \leq \rho e^{h(r_v)} \leq r'_v e^{h(r_v)} = r''_v,$$

so that r lies in E_0 contrary to hypothesis. Thus (3.3) must be false and so (3.1) holds for r in E_1 and $h = \mp h(r)$. Since $N(r)$ increases with r , (3.1) also holds for $|h| \leq h(r)$ and Lemma 1 is proved.

From now on we shall call normal those values of r which satisfy (3.1) for a suitable constant α as well as (1.12). Since the exceptional set in (3.1) has finite logarithmic measure, the conclusions of Theorem 1 to 4 will remain with this restricted notion of normality.

3.1 Estimates for the terms far from the maximum term. Our main result in this section is

LEMMA 2. *Suppose that r is normal in the sense of Theorems 2 or 3 or the case $p > 2$ of Theorem 4. We write $N = N(r)$ and suppose that (3.1) holds with a suitable α . Suppose that γ is a positive constant and write*

$$(3.4) \quad k = \left[\left\{ \frac{\gamma}{b(N)} \log \frac{1}{b(N)} \right\}^{1/2} \right]$$

where $[x]$ denotes the integral part of x . Further suppose that

$$|\log(\rho/r)| \leq 2k^{-1}, \text{ and write } \mu_0(\rho) = |a_N| \rho^N.$$

Then we have for any fixed real q and $\gamma_1 < \gamma$

$$(3.5) \quad \sum_{|n-N| \geq k} n^q |a_n| \rho^n = o\{\mu_0(\rho) N^q b(N)^{(1/2)\gamma_1 - (1/2)}\}$$

uniformly as ρ and r tend to infinity subject to the above inequalities.

Let η be a constant, $0 < \eta \leq \frac{1}{2}$, and assume first that $n \geq (1 + \eta)N$. We choose a fixed $\alpha \leq \frac{1}{2}\eta$ in Lemma 1 and write

$$\rho_1 = r \exp(N^{-\alpha}).$$

Let M be the central index for ρ_1 , so that we have by Lemma 1

$$N \leq M \leq (1 + \alpha)N, \text{ and } |a_n| \rho_1^n \leq |a_M| \rho_1^M.$$

Thus $n - M \geq \frac{1}{2}\eta n$. Also

$$\begin{aligned} \frac{|a_n| \rho^n}{\mu_0(\rho)} &= \frac{|a_n| \rho^n}{|a_N| \rho^N} = \frac{|a_n| \rho^n}{|a_M| \rho_1^M} \cdot \frac{|a_M| r^M}{|a_N| r^N} \cdot \left(\frac{\rho_1}{r}\right)^{M-n} \cdot \left(\frac{\rho}{r}\right)^{n-N} \\ &\leq \left(\frac{\rho_1}{r}\right)^{M-n} \left(\frac{\rho}{r}\right)^{n-N} \leq \exp\{-\frac{1}{3}\eta n N^{-\alpha} + n |\log(\rho/r)|\}. \end{aligned}$$

From the hypotheses of Lemma 2 it follows that

$$|\log(\rho/r)| \leq 2k^{-1} \leq o\{N^{-1/4}\}$$

with the hypotheses of Theorem 2 and 3 and

$$k^{-1} = o\{N^{(2-p)/[3(p-1)]}\}$$

in the case of Theorem 4. By choosing

$$(3.6) \quad \alpha = \frac{1}{3} \frac{p-2}{p-1}, \quad \text{or} \quad \alpha = \frac{1}{2}\eta,$$

we can thus ensure that when r and N are large

$$\frac{|a_n| \rho^n}{\mu_0(\rho)} \leq \exp\left\{-\frac{\eta n}{6} N^{-\alpha}\right\}.$$

We now set $t = \exp(-\eta N^{-\alpha}/6)$ and deduce that for large normal r

$$\begin{aligned} \sum_{n > (1+\eta)N} n^a |a_n| \rho^n &= O\left\{\mu_0(\rho) \sum_{n=N}^{\infty} n^a t^n\right\} = O\{N^a \mu_0(\rho) t^N / (1-t)\} \\ &= O(\mu_0(\rho) N^{-\beta}) \end{aligned}$$

for every positive β .

Suppose next that $n \leq (1-\eta)N$. In this case we write

$$\rho_1 = r \exp(-N^{-\alpha})$$

and proceed as above. We deduce that $(1-\alpha)N \leq M \leq N$ and

$$\begin{aligned} \frac{|a_n| \rho^n}{\mu_0(\rho)} &\leq \exp\left\{-\frac{1}{2}\eta N \cdot N^{-\alpha} + N |\log(\rho/r)|\right\} \\ &\leq \exp\left\{-\frac{1}{2}\eta N^{1-\alpha}\right\}, \end{aligned}$$

if α is given by (3.6) and N is large. Thus

$$\sum_{n \leq (1-\eta)N} n^a |a_n| \rho^n = o[\mu_0(\rho) N^{1+\alpha} \exp(-\frac{1}{2}\eta N^{1-\alpha})] = o[\mu_0(\rho) N^{-\beta}],$$

for every positive β . Thus

$$(3.7) \quad \sum_{|n-N| > \eta N} n^a |a_n| \rho^n = o\{\mu_0(\rho) N^{-\beta}\}$$

for every positive β .

Given $\varepsilon > 0$, we now choose η so small that

$$b(N+|p|) > (1-\varepsilon)b(N) \quad \text{for} \quad |p| \leq \eta N, \quad \text{and} \quad (1-\eta)^{-|a|} < 1+\varepsilon,$$

which is always possible under the hypotheses of Theorems 2, 3, 4. We also suppose that $re^{-t} \leq \rho \leq re^t$, where $t = 2k^{-1}$. Then (2.4) yields for $n = N+p$, $|p| < \eta N$,

$$\frac{n^a |a_n| \rho^n}{\mu_0(\rho)} \leq (1+\varepsilon) N^a e^{t|p|-bp^2} \quad \text{where} \quad b = \frac{1}{2}(1-\varepsilon)b(N).$$

Thus if k satisfies (3.4) we deduce from this and (3.7) that

$$(3.8) \quad \sum_{|n-N| \geq k} n^a |a_n| \rho^n \leq 2(1+\varepsilon) N^a \mu_0(\rho) \left\{ \sum_{p=k}^{\infty} e^{pt-bp^2} + o(N^{-\beta}) \right\}.$$

Our hypotheses ensure that, for large r , N is large and b is small, so that t is small compared with bk in view of (3.4). Thus e^{pt-bp^2} decreases with increasing p , and

$$\sum_{p=k}^{\infty} e^{pt-bp^2} \leq \int_{k-1}^{\infty} e^{tx-bx^2} dx.$$

We set $y = xb^{1/2} - t/(2b^{1/2})$, $y_0 = (k-1)b^{1/2} - t/(2b^{1/2})$, and deduce that

$$\int_{k-1}^{\infty} e^{tx-bx^2} dx = b^{-1/2} e^{(t^2/4b)} \int_{y_0}^{\infty} e^{-y^2} dy,$$

and

$$\int_{y_0}^{\infty} e^{-y^2} dy = \frac{e^{-y_0^2}}{2y_0} - \int_{y_0}^{\infty} \frac{e^{-y^2}}{2y^2} dy \sim \frac{e^{-y_0^2}}{2y_0}.$$

Thus in view of (3.4) we deduce that

$$\sum_{p=k}^{\infty} e^{pt-bp^2} = O\left\{\frac{e^{-y_0^2}}{b^{1/2}y_0}\right\} = O\left\{\frac{\exp[\frac{1}{2}\gamma(1-\varepsilon)\log b(N)]}{b(N)^{1/2}[\log 1/b(N)]^{1/2}}\right\} = O\{b^{(1/2)\gamma_1-(1/2)}\}$$

since $\gamma_1 < \gamma$ and ε may be chosen as small as we please. Now Lemma 2 follows from (3.8).

We note in particular that

$$\sum_{|n-N| \geq N} |a_n| r^n = o\{\mu(r)\}$$

if $k > (1 + \varepsilon)\{b(N)^{-1} \log 1/b(N)\}^{1/2}$, for some $\varepsilon > 0$, for we can then take $\gamma_1 = 1$ in (3.5).

3.2 Similar estimates for functions of order $(\log r)^2$. If $p = 2$ in Theorem 4 we obtain a simpler and stronger result. This is

LEMMA 3. *If $p = 2$ in Theorem 4 and k is a fixed positive integer then*

$$\sum_{|n-N| \geq k} |a_n| r^n \leq \mu(r)A(\sigma, k),$$

where

$$A(\sigma, k) = 2 \sum_{n=k}^{\infty} e^{-(1/2)\sigma n^2}$$

We note that if $p = 2$ in Theorem 4, then that result yields for $n = N + k$

$$|a_n| r^n \leq \mu(r) \exp\left(-\frac{\sigma}{2} k^2\right).$$

outside set r of upper logarithmic density at most δ , provided that $\delta = 2\sigma ce < 1$. Thus

$$\sum_{|n-N| \geq k} |a_n| r^n \leq 2\mu(r) \sum_{t=k}^{\infty} e^{-(1/2)\sigma t^2}$$

and this proves Lemma 3 in this case.

3.3 Functions of order $(\log r)^p$, when $p < 2$. If $p < 2$ we use a different technique

due essentially to Valiron [21, p. 42]. The following result due to Barry [1] will be useful in the sequel, although it is less precise than Lemmas 2 and 3.

LEMMA 4. *Suppose that $f(z)$ is an integral function such that*

$$\overline{\lim}_{r \rightarrow \infty} \frac{\log \log M(r)}{\log \log r} = p < 2.$$

Then if $0 < \eta < 2 - p$, we have

$$\sum_{n \neq N} |a_n| r^n < \mu(r) \exp\{-(\log r)^\eta\}$$

outside a set of r of logarithmic density zero.

We choose $\varepsilon > \eta$, and $q > p$, such that $\varepsilon < 2 - q$. Then it follows from our hypotheses that we have for all sufficiently large r

$$\log \mu(r) < \frac{1}{4}(\log r)^q.$$

Also since $q < 2$, we deduce that

$$N(r) \log r \leq \int_r^{r^2} N(t) \frac{dt}{t} \leq \log \mu(r^2) < \frac{1}{4}(\log r^2)^q < (\log r)^q,$$

so that

$$\log r_N > N^{1/(q-1)}, \quad N > N_0.$$

We now define k_N by the equation

$$\log k_N = 2(\log r_N)^\varepsilon$$

and call the set of r for which

$$\frac{r_N}{k_N} \leq r \leq k_N r_N$$

for some N exceptional. We proceed to show that the set of exceptional r has logarithmic density zero. To see this, suppose that

$$\frac{r_N}{k_N} \leq r \leq \frac{r_{N+1}}{k_{N+1}}.$$

Then the total logarithmic measure of the exceptional ρ , such that $1 \leq \rho \leq r$ is at most

$$\sum_{n=1}^N 2 \log k_n \leq 2N \log k_N \leq 4(\log r_N)^{q-1+\varepsilon} = o(\log r_N) = o(\log r),$$

as required.

Suppose next that r is normal, so that

$$k_N r_N < r < \frac{r_{N+1}}{k_{N+1}}$$

for some N , and write $r/r_N=c_1$, $r_{N+1}/r=c_2$. Then we have for $n < N$

$$|a_n| r^n \leq a_N r_N^N,$$

so that

$$|a_n| r^n \leq |a_N| r^N \left(\frac{r}{r_N}\right)^{n-N} = c_1^{n-N} \mu(r),$$

so that

$$\sum_{n < N} |a_n| r^n \leq \mu(r) \sum_{k=1}^{\infty} c_1^{-k} \leq \frac{\mu(r)}{c_1 - 1},$$

for large r . Similarly,

$$\sum_{n > N} |a_n| r^n \leq \frac{\mu(r)}{c_2 - 1}.$$

From the fact that r is normal and the definition of k_N , we deduce that

$$\frac{1}{c_1 - 1} + \frac{1}{c_2 - 1} = O\{\exp - (\log r)^{\epsilon}\} = o\{\exp - (\log r)^{\eta}\},$$

and Lemma 4 follows.

4. Maximum modulus and maximum term. It follows from Lemmas 2 to 4 that in the series for $f(z)$ we can neglect those terms whose index is not near $N(r)$. By summing the estimates for the remaining terms we obtain a bound for $M(r)$ in terms of $\mu(r)$. We start by investigating the test functions.

LEMMA 5. *Suppose that $F(r)$ is any one of the test functions used for the purpose of proving Theorems 2, 3 and the case $p > 2$ of Theorem 4. Then if $\mu_1(r)$ denotes the maximum term and $N=N_1(r)$ the central index of $F(r)$, and if $b(N)$ is defined as in Theorems 2 to 4, we have†*

$$F(r) \sim \mu_1(r) \{2\pi/b(N_1(r))\}^{1/2}, \quad r \rightarrow \infty.$$

We write

$$F(r) = \sum_0^{\infty} \alpha_n r^n$$

and note that as in Lemma 2 we have

$$(4.1) \quad \sum_{|n-N| \geq k} \alpha_n r^n = o\{\mu_1(r)\}, \quad \text{as } r \rightarrow \infty,$$

if k is given by (3.4) with a suitable constant γ . In all these cases $k(N)=o(N)$. Thus if $r=\rho_N$, we have for all the test functions

$$\alpha'(t) = (1+o(1))\alpha'(N), \quad \text{as } N, t \rightarrow \infty, \quad \text{while } |t-N| \leq k.$$

Thus in this case, (2.2) can be sharpened to

$$\frac{\alpha_n}{\alpha_N} \rho_N^{n-N} = \exp\{-\frac{1}{2}(n-N)^2 \alpha'(N)(1+o(1))\}, \quad |n-N| \leq k.$$

† For a different class of functions satisfying a similar inequality see [7].

Hence, given $\varepsilon > 0$, we see that for all sufficiently large N

$$\sum_{|n-N| \leq k} \alpha_n(\rho_N)^n \text{ lies between } \alpha_N \rho_N^N \sum_{|t| \leq k} \exp\{\frac{1}{2}t^2 \alpha'(N)(1 \mp \varepsilon)\}.$$

Here

(4.2)
$$\alpha'(N) = -b(N).$$

We write $c = c(N) = -\frac{1}{2}\alpha'(N)(1 \mp \varepsilon)$, and note that with our hypotheses c is small if N is large. Thus

$$\begin{aligned} \sum_{|t| \leq k} \exp(-ct^2) &= (1 + o(1)) \int_{-k}^k e^{-cx^2} dx = \frac{1 + o(1)}{\sqrt{c}} \int_{-k\sqrt{c}}^{k\sqrt{c}} e^{-y^2} dy \\ &= (1 + o(1))(\pi/c)^{1/2}, \end{aligned}$$

since in view of (3.4) $k\sqrt{c} \rightarrow \infty$, as $N \rightarrow \infty$. Since ε can be chosen as small as we please, we deduce that

$$\sum_{|n-N| \leq k} \alpha_n(\rho_N)^n \sim \alpha_N \rho_N^N \{2\pi/b(N)\}^{1/2}.$$

Also if $\rho_{N-1} \leq r \leq \rho_{N+1}$, and $|t| \leq k$, we see that

$$\left| \log \left(\left(\frac{r}{\rho_N} \right)^t \right) \right| \leq k \left| \log \frac{\rho_N}{\rho_{N-1}} \right| \sim k\alpha'(N) \rightarrow 0, \text{ as } N \rightarrow \infty.$$

Thus

$$\frac{\sum_{|n-N| \leq k} \alpha_n r^n}{\alpha_N r^N} \sim \frac{\sum_{|n-N| \leq k} \alpha_n \rho_N^n}{\alpha_N \rho_N^N} \sim \{2\pi/b(N)\}^{1/2}.$$

Further if $\rho_N \leq r \leq \rho_{N+1}$, the central index of $F(r)$ is either N or $N+1$, and for all our test functions $b(N) \sim b(N+1)$. Thus

$$\sum_{|n-N| \leq k} \alpha_n r^n \sim \mu_1(r) \{2\pi/b(N)\}^{1/2}$$

and in view of (4.1) we deduce Lemma 5.

It is sometimes of interest to have an expression for N , and hence $b(N)$ in terms of $\mu_1(r)$. This can be deduced from (1.8), (2.1) and (4.2). Thus we have in the case of Theorem 2,

$$b(N) = -\alpha'(N) = \{KN \log N \cdots (\log_{t+1} N)^{1+\delta}\}^{-1},$$

$$\alpha(N) = \frac{1}{\delta K} (\log_{t+1} N)^{-\delta} + c_1,$$

$$\rho_N = c_2 \exp\left\{-\frac{1}{\delta K} (\log_{t+1} N)^{-\delta}\right\},$$

where $c_1, c_2 \cdots$ denote positive constants.

We denote by $e_l(x)$ the l times iterated exponential functions. Then for $\rho_N < r \leq \rho_{N+1}$, we deduce

$$N(r) \sim N = e_{i+1} \left\{ \frac{c_3 + o(1)}{(c_2 - r)^{1/\delta}} \right\},$$

and this in turn yields on integrating by parts

$$\begin{aligned} \log \mu(r) &= \int_{r_0}^r N(t) \frac{dt}{t} + O(1) \\ &\sim c_4 N \{ \log N \cdots \log_i N \cdots (\log_{i+1} N)^{(\delta+1)} \}^{-1}, \end{aligned}$$

Thus in this case Lemma 5 yields

$$(4.3) \quad F(r) \sim c_5 \mu(r) (\log \mu(r))^{1/2} \log_2 \mu(r) \cdots \log_{i+1} \mu(r) (\log_{i+2} \mu(r))^{1+\delta}.$$

In the case of Theorem 3, a much simpler analysis yields

$$\alpha'(N) = -b(N) = -c/N$$

$$\alpha(t) = -c \log t + c_6$$

$$\rho_n = c_7 n^c,$$

$$N(r) \sim c_8 r^{1/c},$$

$$\log \mu(r) \sim cN(r) = c^2/b(N).$$

Thus in this case we obtain from Lemma 5

$$(4.4) \quad F(r) \sim \frac{1}{c} \mu_1(r) \{2\pi \log \mu_1(r)\}^{1/2}.$$

Finally in the case of Theorem 4

$$\alpha'(N) = -b(N) = -\frac{\sigma}{p-1} N^{(2-p)/(p-1)},$$

$$\alpha(N) = -\sigma N^{1/(p-1)}$$

$$\rho_n = c_9 \exp\{\sigma N^{1/(p-1)}\},$$

$$N(r) \sim \left(\frac{1}{\sigma} \log r\right)^{p-1}$$

$$\log \mu(r) \sim \frac{1}{p} N(r) \log r \sim \frac{\sigma}{p} (N(r))^{p/(p-1)}.$$

Thus in this case Lemma 5 yields

$$(4.5) \quad F(r) \sim c_{10} \mu_1(r) \{ \log \mu_1(r) \}^{(p-2)/(2p)},$$

where

$$(4.6) \quad c_{10} = (2\pi)^{1/2} p^{(p-2)/(2p)} (p-1)^{1/2} \sigma^{(1-p)/p}.$$

4.1 **The main results.** Using (1.12) we can easily deduce from Lemma 5 and (4.3) to (4.5) corresponding inequalities for general functions when r is normal. We have in fact.

THEOREM 5. *With the hypotheses of Theorems 2, 3, and 4 when $p > 2$, we have, given $\varepsilon > 0$,*

$$(4.7) \quad M(r, f) < (1 + \varepsilon)\mu(r) \left\{ \frac{2\pi}{b(N)} \right\}^{1/2}$$

for all sufficiently large normal r .

If $p = 2$ in Theorem 4, we have with the notation of Lemma 3 for $|z| = r$

$$(4.8) \quad \mu(r)(1 - A(\sigma, 1)) \leq |f(z)| \leq \mu(r)(1 + A(\sigma, 1))$$

and if $p < 2$ and $\varepsilon > 0$, we have

$$(4.9) \quad |f(z)| = \mu(r) \{ 1 + o[\exp - (\log r)^{2-p-\varepsilon}] \}.$$

Since (4.8) and (4.9) follow immediately from Lemma 3 and 4 respectively it is enough to prove (4.7). Let $F(r)$ be the appropriate test function for which r is normal. Then for normal r we deduce from (1.10) that

$$(4.10) \quad \frac{|a_n| r^n}{\mu(r)} \leq \frac{\alpha_n \rho_N^n}{\mu_1(\rho_N)},$$

and summing from 0 to ∞ , we deduce that

$$(4.11) \quad \frac{M(r, f)}{\mu(r)} \leq \sum_0^\infty \frac{|a_n| r^n}{\mu(r)} \leq \sum_0^\infty \frac{\alpha_n \rho_N^n}{\mu_1(\rho_N)} = \frac{F(\rho_N)}{\mu_1(\rho_N)} \sim \left(\frac{2\pi}{b(N)} \right)^{1/2},$$

which yields (4.7).

It is not difficult to deduce from (4.5) inequalities in terms of $\mu(r)$ alone. For this purpose we assume that $a_0 = 1$. This result may be achieved by adding a constant to $f(z)$ which evidently does not alter any of our asymptotic relations. Then we may put $n = 0$ in (4.10) and deduce that

$$\frac{1}{\mu(r)} \leq \frac{\alpha_0}{\mu_1(\rho_N)},$$

so that

$$(4.12) \quad \mu_1(\rho_N) \leq \alpha_0 \mu(r).$$

Using the asymptotic relations (4.3) to (4.5) and (4.12), which shows that

$$(4.13) \quad \log \mu_1(\rho_N) \leq \log \mu(r) + O(1),$$

we obtain

THEOREM 6. *We have for large normal r with the hypotheses of Theorem 2*

$$(4.14) \quad M(r) < \mu(r)(\log \mu(r))^{1/2} \log_2 \mu(r) \cdots \log_l \mu(r) [\log_{l+1} \mu(r)]^{1+\delta}.$$

With the hypotheses of Theorem 3 we have

$$(4.15) \quad M(r) < \frac{1}{c+o(1)} \mu(r) \{2\pi \log \mu(r)\}^{1/2},$$

and with those of Theorem 4 with $p > 2$

$$(4.16) \quad M(r) < (c_{10} + o(1)) \mu(r) (\log \mu(r))^{(p-2)/(2p)},$$

where c_{10} is defined by (4.6).

To prove (4.15) for instance, we note that (4.11) and (4.4) yield

$$\frac{M(r, f)}{\mu(r)} \leq \frac{F(\rho_N)}{\mu_1(\rho_N)} \leq \frac{1}{c+o(1)} \{2\pi \log \mu_1(\rho_N)\}^{1/2}$$

and using (4.13) we deduce (4.15). The other two inequalities follow similarly. It follows from Theorem 3, that we may take for c any quantity less than ρ^{-1} in (4.15). If $\rho' > \rho$, we choose c so that $\rho < c^{-1} < \rho'$, and deduce from (4.15) and Theorem 3 that we have

$$(4.17) \quad M(r) < \rho' \mu(r) \{2\pi \log \mu(r)\}^{1/2}$$

on a set of lower logarithmic density at least $1 - c\rho$. Letting c^{-1} tend to ρ' , we deduce that the set where (4.17) holds has lower logarithmic density at least $1 - \rho/\rho'$. On the other hand (4.4) shows that if $\rho' < \rho$ the set where (4.17) holds may be bounded.

The inequality (4.14) is also best possible in the sense that δ cannot be replaced by zero. This can be shown by taking

$$\alpha(t) = -\log_{l+1}(t)$$

for large t . The corresponding test function is an integral function for which

$$\alpha'(t) = -\{t \log t \cdots \log_l t\}^{-1} = -b(t),$$

so that

$$N(r) \sim e_l(r), \quad \log \mu(r) \sim N(r) \{\log N(r) \cdots \log_l N(r)\}^{-1},$$

and so Lemma 5 yields for the corresponding test function $F(r)$

$$F(r) \sim \mu(r) (2\pi)^{1/2} (\log \mu(r))^{1/2} \log_2 \mu(r) \cdots \log_{l+1} \mu(r).$$

The inequalities (4.14) and (4.15) were proved by Wiman [22] to hold for some arbitrarily large r . Valiron [19] showed that (4.14) holds outside a set of finite logarithmic measure. The argument for deducing (4.15) for normal r and hence on a set of positive lower logarithmic density is implicit in the work of Clunle [4].

5. The minimum modulus of functions of small growth. We proceed to prove the following result which goes back to Valiron [21, p. 42].

THEOREM 7. *Suppose that $f(z)$ is an integral function, such that*

$$(5.1) \quad \overline{\lim}_{r \rightarrow \infty} \frac{\log M(r, f)}{(\log r)^2} \leq c < \frac{1}{4e}.$$

Then if

$$m(r, f) = \inf_{|z|=r} |f(z)|,$$

and $0 < 4ec \leq \delta < 1$, we have outside a set of upper logarithmic density at most δ

$$(5.2) \quad \frac{m(r, f)}{M(r, f)} > K(\delta, c) = \frac{1 - 2.2\tau}{1 + 2.2\tau}$$

where $\tau = \exp\{-\delta/(4ce)\}$.

We define σ by $\delta = 2ce\sigma$, so that $\sigma \geq 2$. Then Lemma 3 shows that

$$\frac{m(r, f)}{M(r, f)} \geq \frac{1 - A(\sigma, 1)}{1 + A(\sigma, 1)}$$

for a set of r of lower logarithmic density at least $1 - \delta$. Also

$$A(\sigma, 1) = 2 \sum_{k=1}^{\infty} e^{-(1/2)\sigma k^2} = 2\tau(1 + \tau^3 + \tau^8 + \dots)$$

where $\tau = e^{-(1/2)\sigma}$. In particular, since $\sigma \geq 2$, we see that

$$A(\sigma, 1) \leq 2\tau \left(1 + e^{-3} + \frac{e^{-8}}{1 - e^{-1}} \right) = 2.100 \dots \tau$$

Thus

$$\frac{m(r, f)}{M(r, f)} \geq \frac{1 - 2.2\tau}{1 + 2.2\tau}$$

as required.

A corresponding result for arbitrary positive δ, c was proved by Barry [1] with

$$(5.3) \quad K(\delta, c) = \exp\left\{-\frac{\pi^2 c(2-\delta)}{\delta}\right\}.$$

However this beautiful result in which the constant π^2 is best possible is proved by a quite different method and so we omit the proof. Barry [1] also obtains rather sharper estimates than (5.2) for a sequence of r when c is small, but at the cost of density.

We also note the following result of Barry [1] which follows easily from Theorem 7.

THEOREM 8. *If (5.1) holds with $c=0$, then*

$$\frac{m(r, f)}{M(r, f)} \rightarrow 1$$

as $r \rightarrow \infty$ on a set of logarithmic density 1.

In fact it follows from (5.2) in this case that for every positive ϵ the set $E(\epsilon)$ on which

$$\frac{m(r, f)}{M(r, f)} > 1 - \epsilon$$

has logarithmic density one. For given $\delta < 1$, we may choose c so small that $K(\delta, c) > 1 - \varepsilon$ in (5.2) so that the complement of $E(\varepsilon)$ has upper logarithmic density at most δ , and so this density must be zero. Since this is true for every ε , Theorem 8 follows. (For details see Barry [1, p. 477].)

If $p < 2$ we can prove considerably more. In fact Lemma 4 yields at once

THEOREM 9. *If $f(z)$ is an integral function such that*

$$\lim_{r \rightarrow \infty} \frac{\log \log M(r)}{\log \log r} = p < 2,$$

then if $0 < \eta < 2 - p$ we have

$$\frac{m(r)}{M(r)} > 1 - \exp\{-(\log r)^\eta\}$$

outside a set of logarithmic density zero.

6. Behaviour near the local maximum. The Wiman-Valiron Theory can be used to obtain very precise estimates for the behaviour of the function near points on $|z|=r$, where $|f(z)|$ is maximal or nearly maximal, when r is normal. In order to develop this theory we first establish a result on the behaviour of a regular function near a point of maximum modulus. Our result is

LEMMA 6. *Suppose that $f(z)$ is an integral function and that $|z_0|=r$, $|f(z_0)|=M(r, f)$. Then we have except possibly for isolated values of r*

$$(6.1) \quad z \frac{d}{dz} \log f(z) = a(r), \quad \left| \left(z \frac{d}{dz} \right)^2 \log f(z) \right| \leq b(r)$$

for $z=z_0$, where $a(r)$, $b(r)$ are defined by (1.5).

We set $z_0=re^{i\theta}$. Then since $|f(z_0)|$ is maximal, we deduce that

$$(6.2) \quad \frac{\partial}{\partial \theta} \log |f(re^{i\theta})| = \operatorname{Im} z_0 \frac{f'(z_0)}{f(z_0)} = 0.$$

Thus z_0 is one of the finite number of points on $|z|=r$, where $zf'(z)/f(z)$ is real. In a neighbourhood, $r_0 - \varepsilon < r < r_0 + \varepsilon$, of a fixed r_0 , the different values of $\log |f(re^{i\theta})|$ at the corresponding points $\theta_v(r)$ satisfying (6.2) are either identical or distinct, except for isolated values of r_0 . Hence, except for such values of r_0 , for all r sufficiently close to r_0 the maximum modulus is attained at points $re^{i\theta(r)}$, where $\theta(r)$ is the solution of (6.2) which coincides with a fixed solution $\theta(r_0)=\theta_0$, when $r=r_0$, provided that $r_0 \exp(i\theta_0)$ is a point of maximum modulus.

We now write $z=z_0e^\tau$

$$(6.3) \quad \log f(z) = \phi(\tau) = \phi(0) + \alpha\tau + (\beta + i\gamma)\tau^2 + \dots$$

where the expansion is valid for small τ . In view of (6.2) it follows that

$$\alpha = z_0 \frac{f'(z_0)}{f(z_0)}$$

is purely real. Next we choose $\tau = \sigma + i\theta$, where $\theta = \theta(r_0 e^\sigma) - \theta_0$, so that z is a point of maximum modulus. We assume that the maximum modulus curve does not touch $|z| = r$ at z_0 , which is true except for isolated values of r . Then it follows from (6.3) that

$$\log \frac{M(r_0 e^\sigma)}{M(r_0)} = \log \left| \frac{f(z)}{f(z_0)} \right| = \alpha\sigma + O(\sigma^2),$$

so that

$$a(r_0) = \frac{d}{d\sigma} \log M(r_0 e^\sigma) = \alpha = z_0 \frac{f'(z_0)}{f(z_0)},$$

which is the first conclusion of (6.1). To obtain the second inequality we assume that $\beta \neq 0$, which is true except for isolated values of r and choose $\theta = -\gamma\sigma/\beta$, $\tau = \sigma + i\theta$. Since $\beta = -(\partial/\partial\theta)^2 \log |f(r_0 e^{i\theta})| \geq 0$ in any case, we may thus assume $\beta > 0$. Taking real parts in (6.3) we deduce

$$\begin{aligned} \log M(r_0 e^\sigma) &\geq \log |f(z_0 e^\sigma)| = \log |f(z_0)| + \alpha\sigma + \beta(\sigma^2 - \theta^2) - 2\gamma\sigma\theta + O(\sigma^3) \\ &= \log M(r_0) + \alpha\sigma + \frac{\beta^2 + \gamma^2}{\beta} \sigma^2 + O(\sigma^3). \end{aligned}$$

We deduce that

$$\begin{aligned} b(r_0) &= \left(\frac{d}{d\sigma}\right)^2 \log M(r_0 e^\sigma) \geq \frac{2(\beta^2 + \gamma^2)}{\beta} \geq 2(\beta^2 + \gamma^2)^{1/2} \\ &= \left| \left(z \frac{d}{dz}\right)^2 \log f(z) \right| \end{aligned}$$

at $z = z_0$. This proves the second inequality in Lemma 6 and completes the proof of that Lemma.

We need some more subsidiary results.

LEMMA 7. *Suppose that $P(z)$ is a polynomial of degree m , and $|P(z)| \leq M$, for $|z| \leq r$. Then if $R \geq r$, we have*

$$|P'(z)| \leq \frac{eMmR^{m-1}}{r^m}, \quad |z| \leq R.$$

In fact it follows from a classical result of Bernstein [2, see also 13 p. 221] that the result holds without the factor e . However this does not greatly affect our results and we can give a simple proof of Lemma 7.

We note first that $P(z)/z^m$ remains regular at ∞ and so we can apply the maximum principle to this function in $|z| > r$ and deduce that

$$|P(z)| \leq M \left(\frac{|z|}{r}\right)^m, \quad |z| > r.$$

Now we apply Cauchy's inequality and deduce that for $|z| \leq R, h=R/m$

$$|P'(z)| \leq \frac{1}{h} \max_{|\xi-z| \leq h} |P(\xi)| \leq \frac{M}{hr^m} (R+h)^m = \frac{MmR^{m-1}}{r^m} \left(1 + \frac{1}{m}\right)^m.$$

This yields the required result. We deduce

LEMMA 8. *With the hypotheses of Lemma 7 if $|z_0| \leq r, |P(z_0)| \geq \eta M$, where $0 < \eta \leq 1$, then we have*

$$\frac{1}{2} |P(z_0)| < |P(z)| < \frac{3}{2} |P(z_0)|$$

for $|z-z_0| < \eta r/(8m)$.

We deduce from Lemma 7 that for $|z-z_0| \leq \eta r/(8m)$

$$|P'(z)| \leq \frac{eMm}{r^m} r^{m-1} \left(1 + \frac{1}{8m}\right)^{m-1} < \frac{4mM}{r}.$$

Thus in this range

$$|P(z) - P(z_0)| = \left| \int_{z_0}^z P'(\xi) d\xi \right| \leq \frac{4Mm}{r} |z-z_0| \leq \frac{1}{2} M\eta \leq \frac{1}{2} |P(z_0)|.$$

6.1 Statement and proof of the main results. We can now state and prove our first result on local behaviour†

THEOREM 10. *Suppose that $f(z)$ is an integral function and that r is normal in the sense of one of the Theorems 2, 3, 4, provided that $p > 2$ in the latter case. In this case we also set $\gamma = 10(p-1)/(p-2)$, while in the other cases we set $\gamma = 10$. We write N for $N(r)$, suppose that $|z_0| = r$ and*

$$(6.4) \quad |f(z_0)| \geq \eta M(r, f) \quad \text{where} \quad N^{-3} \leq \eta \leq 1,$$

and define k by (3.4). Then if

$$(6.5) \quad z = z_0 e^\tau, \quad \text{and} \quad |\tau| \leq \eta/(30k)$$

we have

$$(6.6) \quad \log \frac{f(z)}{f(z_0)} = (N + \phi_1)\tau + \phi_2\tau^2 + \delta(\tau),$$

where

$$(6.7) \quad |\phi_j| \leq \frac{4}{\pi} (18k/\eta)^j, \quad j = 1, 2, \quad \text{and} \quad |\delta(\tau)| \leq 4(18k|\tau|/\eta)^3.$$

We apply Lemma 2 with γ defined as in Theorem 10. Then we have for $\gamma_1 < \gamma$ and $|z| = \rho$, where $|\rho-r| < r/k$

$$f(z) = \sum_{N-k}^{N+k} a_n z^n + o\{\mu_0(\rho)b(N)^{(1/2)\gamma_1 - (1/2)}\}.$$

† Similar results which are however not quite correct in the dependence of τ upon η were obtained by Clunie [4, Theorem 5 and 5, Theorem 9].

In the case of Theorems 2 and 3, we have

$$b(N) = O(N^{-1}),$$

so that taking $\gamma_1=9$, we deduce

$$(6.8) \quad f(z) = \sum_{N-k}^{N+k} a_n z^n + o\{\mu_0(\rho)N^{-4}\} = \sum_{N-k}^{N+k} a_n z^n + o\{M(\rho, f)N(r)^{-4}\}.$$

In the situation of Theorem 4, we have

$$b(N) = O\{N^{(2-p)/(p-1)}\}$$

so taking $\gamma_1=9(p-1)/(p-2)$, we again deduce (6.8), so that (6.8) holds in all cases.

Thus if $|f(z)| \geq M(\rho, f)N(r)^{-4}$, we have

$$(1+o(1))f(z) = z^{N-k}P(z),$$

where $P(z)$ is a polynomial of degree at most $2k$. To this polynomial we apply Lemma 7. We deduce from (6.8) that we have for $|z|=r$

$$|z^{N-k}P(z)| \leq (1+o(1))M(r, f),$$

so that if ε is a fixed positive number and

$$M_0 = (1+\varepsilon)r^{k-N}M(r, f),$$

we have, when r is sufficiently large

$$(6.9) \quad |P(z)| \leq M_0, \quad |z| = r.$$

Also (6.4) and (6.8) show that

$$f(z_0) = z^{N-k}P(z_0) + o\{M(r, f)N(r)^{-4}\} = z^{N-k}P(z_0) + o\{f(z_0)\}$$

so that for large r

$$r^{N-k} |P(z_0)| \geq (1-\varepsilon) |f(z_0)| \geq (1-\varepsilon)\eta M(r, f).$$

Thus

$$|P(z_0)| \geq \frac{1-\varepsilon}{1+\varepsilon} \eta M_0.$$

Hence we deduce from Lemma 8 that

$$(6.10) \quad \frac{1}{2} |P(z_0)| < |P(z)| < \frac{3}{2} |P(z_0)| \quad \text{for} \quad |z-z_0| < \frac{1-\varepsilon}{1+\varepsilon} \frac{\eta r}{16k}.$$

Also for this range of z we have (6.8) so that

$$\begin{aligned} \frac{f(z)}{z^N} &= \frac{P(z)}{z^k} + o\left\{\frac{\mu_0(\rho)}{\rho^N} N(r)^{-4}\right\} = \frac{P(z)}{z^k} + o\{a_N N^{-4}\} \\ &= \frac{P(z)}{z^k} + o\left\{\frac{M(r, f)}{r^N} N^{-4}\right\} = \frac{P(z)}{z^k} + o\left\{\frac{M_0}{r^k N^4}\right\} = \frac{(1+o(1))P(z)}{z^k}, \end{aligned}$$

since for large k

$$\frac{14}{15} \leq \left(1 - \frac{1}{16k}\right)^k \leq \left(\frac{\rho}{r}\right)^k = \left|\frac{z}{z_0}\right|^k \leq \left(1 + \frac{1}{16k}\right)^k \leq \frac{16}{15}.$$

Using this and (6.10) we deduce finally that

$$(6.11) \quad |f(z)| = |f(z_0)| \left|\frac{z}{z_0}\right|^N (1+H),$$

where

$$|H| < \frac{3}{5}, \quad \text{for } |z-z_0| < \frac{\eta r}{17k}.$$

We now consider

$$\phi(\tau) = \log f(z_0 e^\tau) - N\tau - \log f(z_0)$$

in the disk

$$|\tau| \leq \tau_0 = \frac{\eta}{18k}.$$

Then if $\phi(\tau) = u + iv$, and r is large, so that k is large, we deduce from (6.11) that

$$|u| \leq \log \frac{5}{2} < 1 \quad |\tau| \leq \tau_0.$$

Also $\phi(0) = 0$. Hence if

$$\phi(\tau) = \sum_1^\infty \phi_n \tau^n, \quad |\tau| < \tau_0,$$

we deduce from subordination [see e.g. 13, p. 221] that

$$(6.12) \quad |\phi_n| \leq \frac{4}{\pi} \tau_0^{-n},$$

so that

$$\left| \sum_{n=3}^\infty \phi_n \tau^n \right| \leq \frac{4}{\pi} \frac{|\tau|^3}{\tau_0^2(\tau_0 - |\tau|)}.$$

In particular we deduce that

$$\phi(\tau) = \phi_1 \tau + \phi_2 \tau^2 + \delta(\tau),$$

where

$$(6.13) \quad |\delta(\tau)| < \frac{10}{\pi} \left(\frac{|\tau|}{\tau_0}\right)^3 \quad \text{for } |\tau| \leq \frac{3}{5}\tau_0 = \frac{\eta}{30k}.$$

On combining (6.12) and (6.13) we have Theorem 10.

In view of Lemma 6 we also deduce

THEOREM 11. *If $|f(z_0)| = M(r, f)$, so that $\eta = 1$ in Theorem 10, we have $N(r) + \phi_1 = a(r)$, $|\phi_2| \leq \frac{1}{2}b(r)$ in Theorem 10 where $a(r)$, $b(r)$ are defined as in (1.5).*

Theorem 10 asserts in particular that $f(z) \neq 0$ for $|\log(z/z_0)| < \eta/(30k)$. If $f(z)$ has finite order ρ it follows from Theorem 3 that we may take $b(N) = c_1/N$, and so $k = c_2(N(\log N))^{1/2}$ where c_1, c_2 are constants depending on ρ . Also the smaller we take c_1 and so the larger we take c_2 , the smaller does the density of the exceptional set of r become.

6.2. Behaviour of derivatives. The Wiman-Valiron theory also permits us to give good estimates for the derivatives of $f(z)$, when $|z|$ is normal. We proceed to prove†

THEOREM 12. *Suppose that $f(z)$ and r satisfy the hypotheses of Theorem 10, that γ and k are defined as in that Theorem and that*

$$r\left(1 - \frac{1}{40k}\right) < \rho < r\left(1 + \frac{1}{40k}\right).$$

Then if q is a fixed nonnegative integer we have for $|z| = \rho$

$$(6.14) \quad \left(\frac{z}{N}\right)^q f^{(q)}(z) = f(z) + O\left(\frac{k}{N}\right) M(\rho, f).$$

In particular if $\log(\rho/r) = o(k^{-1})$, then

$$(6.15) \quad M(\rho, f^{(q)}) = \left(\frac{N(r)}{\rho}\right)^q \left[1 + O\left(\frac{k}{N(r)}\right)\right] M(\rho, f) \sim \left(\frac{N(r)}{r}\right)^q \left(\frac{\rho}{r}\right)^q M(r, f).$$

We write

$$(6.16) \quad f(z) = \sum_{N-k}^{N+k} a_n z^n + \phi(z) = z^{N-k} P(z) + \phi(z).$$

Thus we have by Lemma 2

$$\begin{aligned} \rho^q |\phi^{(q)}(z)| &= \left| \sum_{|n-N| \geq k} a_n n(n-1) \cdots (n-q+1) z^n \right| \\ &\leq \sum_{|n-N| > k} n^q |a_n| \rho^n = o\{\mu_0(\rho) N^q b(N)^{(1/2)\gamma_1 - (1/2)}\}. \end{aligned}$$

for any $\gamma_1 < \gamma$. We again choose $\gamma_1 = .9 \gamma$ and deduce just as in the proof of Theorem 10, that

$$b(N)^{1/2\gamma_1 - 1/2} = O(N^{-4}),$$

so that

$$(6.17) \quad \rho^q |\phi^{(q)}(z)| = o\{\mu_0(\rho) N^{q-4}\}.$$

Again repeated application of Lemma 7 shows that if $P(z)$ is the polynomial occurring in (6.16) then for any fixed $\nu \geq 0$, and $|z| = \rho$, we have

$$|P^{(\nu)}(z)| = O(k/r)^\nu M_0,$$

† A result of this type is (not quite correctly) stated and proved by Clunie [5, Theorem 8].

where M_0 is the quantity in (6.9). Thus

$$\begin{aligned}
 \left(\frac{d}{dz}\right)^a z^{N-k} P(z) &= \sum_{\nu=0}^a \binom{a}{\nu} \frac{(N-k)!}{(N-k-q+\nu)!} z^{N-k-a+\nu} P^{(\nu)}(z) \\
 (6.18) \qquad &= \frac{(N-k)!}{(N-k-q)!} z^{N-k-a} \{P(z) + O(k/N)M_0\} \\
 &= \frac{(N-k)!}{(N-k-q)!} z^{-a} \{f(z) + O(\mu_0(\rho)N^{-4}) + O(\rho^{N-k}M_0k/N)\}
 \end{aligned}$$

in view of (6.16) and (6.17). Now

$$\mu_0(\rho)N^{-4} \leq M(\rho, f)N^{-4} = O\left(\frac{k}{N}\right)M(\rho, f).$$

Also

$$\rho^{N-k}M_0 = (1+\varepsilon)\left(\frac{\rho}{r}\right)^{N-k} M(r, f) = O\left(\frac{\rho}{r}\right)^N M(r, f).$$

Thus combining (6.16), (6.17) and (6.18) we deduce that

$$(6.19) \quad z^a f^{(a)}(z) = \frac{(N-k)!}{(N-k-q)!} \left\{ f(z) + O\left(\frac{k}{N}\right)M(\rho, f) + O\left(\frac{\rho}{r}\right)^N \left(\frac{k}{N}\right)M(r, f) \right\}.$$

Next we chose z_0 so that $|f(z_0)| = M(r, f)$ and take $\eta = 1$, $\tau = \log(\rho/r)$. Then (6.6) gives

$$\begin{aligned}
 \log \left| f\left(\frac{\rho}{r} z_0\right) \right| &= \log |f(z_0)| + N\tau + O(1), \\
 \tau &= O(1)/k,
 \end{aligned}$$

so that

$$\log M(\rho, f) \geq \log M(r, f) + N \log \frac{\rho}{r} + O(1),$$

and hence

$$\left(\frac{\rho}{r}\right)^N M(r, f) = O\{M(\rho, f)\}.$$

Thus (6.19) yields

$$z^a f^{(a)}(z) = \frac{(N-k)!}{(N-k-q)!} \left\{ f(z) + O\left(\frac{k}{N}\right)M(\rho, f) \right\} = N^a \left\{ f(z) + O\left(\frac{k}{N}\right)M(\rho, f) \right\},$$

which is (6.14).

We chose z in (6.14) in turn so as to make $|f(z)|$ and $|f^{(a)}(z)|$ maximal and deduce that

$$M(\rho, f^{(a)}) \geq \left\{ 1 + O\left(\frac{k}{N}\right) \right\} \left(\frac{N}{\rho}\right)^a M(\rho, f)$$

and

$$M(\rho, f^{(a)}) \leq \left\{ 1 + O\left(\frac{k}{N}\right) \right\} \left(\frac{N}{\rho}\right)^a M(\rho, f),$$

so that

$$M(\rho, f^{(q)}) = \left(\frac{N}{\rho}\right)^q \left\{1 + O\left(\frac{k}{N}\right)\right\} M(\rho, f).$$

To complete the proof of (6.15) it remains to show that

$$\log M(\rho, f) = \log M(r, f) + N \log \frac{\rho}{r} + o(1).$$

To see this we note that (6.16) and (6.17) yield for our range of ρ

$$\log M(\rho, f) = (N - k) \log \rho + \log M(\rho, P) + o(1).$$

On the other hand it follows from Lemma 7, that

$$M(\rho, P) = M(r, P) \{1 + O(k(\rho - r)/r)\} \sim M(r, P)$$

if $k \log(\rho/r) = o(1)$, and now the second inequality of (6.15) also follows and the proof of Theorem 12 is complete.

6.3. A generalization of Picard's Theorem. We can use the preceding results to prove a result which generalizes Picard's Theorem. This is

THEOREM 13.† *Suppose that $f(z)$ is a transcendental integral function. Then $f(z)$ assumes every value with at most one exception infinitely often and, if such an exceptional value exists, all the derivatives $f^{(q)}(z)$ assume every value except possibly zero infinitely often.*

We note that if $f(z) = e^z + a$, then $f(z) \neq a, f^{(q)}(z) \neq 0$ for any $q \geq 1$. We suppose that the equation $f(z) = 0$ has only a finite number of roots and deduce that for any $q \geq 0$, the equation $f^{(q)}(z) = 1$ has infinitely many roots. This is equivalent to the stated result since if the equations $f(z) = a, f^{(q)}(z) = b$ have only a finite number of roots, where $b \neq a$, if $q = 0$, and $b \neq 0$, if $q > 0$, we may consider $(f(z) - a)/(b - a)$ or $(f(z) - a)/b$ instead of $f(z)$.

Suppose then that $f(z)$ has only a finite number of zeros. Then

$$f(z) = P(z)e^{g(z)},$$

where $P(z)$ is a polynomial and $g(z)$ an integral function. Suppose first that $g(z)$ is a polynomial. Then it is elementary to show that $f(z)$ assumes all values except zero infinitely often [see e.g. 17, p. 279]. Since $f^{(p)}(z)$ takes a similar form, we also deduce that $f^{(p)}(z)$ assumes all values except zero infinitely often in this case.

Suppose next that $g(z)$ is a transcendental integral function. Then we apply Theorem 2 and its consequences with $b(N) = N^{-1}(\log N)^{-3}$, so that we may take in (3.4) and subsequently

$$k = 10[N^{1/2}(\log N)^2],$$

† The case $q = 1$ appears to be due to Pólya-Saxer [15, p. 210] and the general case to Bureau [3].

where $N=N(r)$ is the central index. We note that

$$f'(z) = (P' + Pg')e^g, \quad f'' = (Pg'^2 + 2P'g' + Pg'' + P'')e^g,$$

and prove by induction that

$$f^{(q)}(z) = Q(z)e^g,$$

where $Q(z)$ is a polynomial of degree q in $g'(z)$ and its derivatives, with coefficients that are polynomials in z , and the leading term of $Q(z)$ is Pg'^q .

It now follows from Theorems 10 and 12 that if r is normal, z_0 is so chosen that $|g(z_0)|=M(r, g)$, $|z_0|=r$ and if $|\log z/z_0|=O(N^{-1})$ where $N(r)$ is the central index of $g(z)$, we have

$$g^{(v)}(z) \sim \left(\frac{N}{z}\right)^v g(z) = O\left\{\left(\frac{N}{r}\right)^v M(r, g)\right\}.$$

Thus

$$P(z)g'(z)^q \sim P(z)\left(\frac{N}{z_0}\right)^q g(z)^q.$$

On the other hand

$$(6.20) \quad N(r) = r \frac{d}{dr} \log \mu(r) < \{\log \mu(r)\}^2 \leq (\log M(r))^2$$

outside a set of finite logarithmic measure. In fact if E is the set in $[r_0, \infty]$ where (6.20) is false, we have in view of (1.7)

$$\int_E \frac{dr}{r} \leq \int_E \frac{N(r) dr}{r \log \mu(r)^2} \leq \int_{r_0}^\infty \frac{N(r) dr}{r \log \mu(r)^2} = \frac{1}{\log \mu(r_0)} < \infty.$$

Thus we assume that r is outside this exceptional set and then

$$Q(z) \sim P(z)\left(\frac{N}{z_0}\right)^q g(z)^q,$$

since the other terms in the polynomial for $Q(z)$ only contribute terms of the order $M(r, g)^{q-1+\epsilon}$. We have shown that

$$f^{(q)}(z) \sim P(z)\left(\frac{Ng(z)}{z_0}\right)^q e^{g(z)}, \quad \text{for } \left|\log\left(\frac{z}{z_0}\right)\right| = |\tau| \leq 10/N$$

say. We deduce that in the same disk

$$h(z) = \log f^{(q)}(z) = g(z) + q \log \frac{N}{z_0} + q \log g(z) + \log P(z) + o(1) \sim g(z)$$

in view of (6.20). Hence in this range, if we set $H(z)=\log h(z)$, we deduce that with a suitable choice of $H(z_0)$ we have

$$H(z) = \log g(z) + o(1) = H(z_0) + N\tau + o(1)$$

in view of Theorem 10.

We now apply Rouché's theorem and deduce that if $|w - H(z_0)| < 5$, then the equation $H(z) = w$ has a root for $|N\tau| < 10$, i.e. $|\log(z/z_0)| < 10N^{-1}$. We may choose w of the form $w = \log(2\pi l) + (2m + \frac{1}{2})\pi i$, for some integers l and m_0 . In fact let $H(z_0) = U_0 + iV_0$, so that U_0 is large and positive. Then we may choose l so that

$$|\log(2\pi l) - U_0| < 1, \text{ and } m \text{ so that } |(2m + \frac{1}{2})\pi - V_0| \leq \pi,$$

and this gives $|w - H(z_0)| < 5$ as required. Thus there exists z_1 , such that $H(z_1) = w$, $h(z_1) = e^w = 2\pi il$, $f^{(p)}(z_1) = \exp(h(z_1)) = 1$. Since there are infinitely many such points z_1 , Theorem 13 is proved. It is worth stating that more precise results applying also to meromorphic functions can be obtained by means of Nevanlinna Theory [8, Theorem 3.5] but the present approach is probably more elementary. It also shows that for functions of infinite order the roots are located near the points of maximum modulus. This is false in general for functions of finite order as $f(z) = e^z$ shows.

7. Two Counterexamples: The sigma function. To test the sharpness of the results obtained we consider two examples.

EXAMPLE 1. Let $\sigma(z)$ be the sigma function with zeros at all the lattice points $z_{m,n} = m + ni$. Then

$$p(z) = -\left(\frac{d}{dz}\right)^2 \log \sigma(z) = z^{-2} + \sum'_{m,n} \left\{ \left(\frac{1}{z - z_{m,n}}\right)^2 - \frac{1}{z_{m,n}^2} \right\}$$

and the dash denotes the fact that the term for $m = n = 0$ is to be omitted. Then $p(z)$ is clearly doubly periodic with periods 1 and i .

Also integrating we deduce that

$$\zeta(z) = \frac{\sigma'(z)}{\sigma(z)}$$

satisfies

$$\zeta(z+1) - \zeta(z) = A, \quad \zeta(z+i) - \zeta(z) = -Ai,$$

where A is a real constant. The second equation follows from the first, since by inspection

$$\zeta(z) = \frac{1}{z} + \sum' \left\{ \frac{1}{z - z_{m,n}} + \frac{z}{z_{m,n}^2} \right\}$$

satisfies $\zeta(iz) = -i\zeta(z)$.

Integrating again we deduce that

$$\log \frac{\sigma(z+1)}{\sigma(z)} = Az + B, \quad \log \frac{\sigma(z+i)}{\sigma(z)} = -Aiz + C.$$

Also

$$\sigma(z) = z \exp \prod'_{m,n} \left(1 - \frac{z}{z_{m,n}} \right) \exp \left\{ \frac{z}{z_{m,n}} + \frac{z^2}{2z_{m,n}^2} \right\}$$

is clearly an odd function. So setting $z = -\frac{1}{2}, -\frac{1}{2}i$, we deduce that

$$e^{B-(A/2)} = -1, \quad e^{C-(A/2)} = -1,$$

so that

$$\sigma(z+1) = -e^{A(z+1/2)}\sigma(z), \quad \sigma(z+i) = -e^{-A(z+i/2)}\sigma(z).$$

We now deduce

LEMMA 9. *If $z_2 = z_1 + m + ni$, where m, n are integers then*

$$|\sigma(z_2)| e^{-1/2A|z_2|^2} = |\sigma(z_1)| e^{-1/2A|z_1|^2}.$$

Write $z_1 = x + iy, z_2 = x + 1 + iy$. Then

$$\left| \frac{\sigma(z_2)}{\sigma(z_1)} \right| = |e^{A(z_1+1/2)}| = e^{A(x+1/2)} = e^{1/2A(|z_2|^2 - |z_1|^2)}.$$

Similarly if $z_2 = z_1 + i$

$$\left| \frac{\sigma(z_2)}{\sigma(z_1)} \right| = |e^{-Ai(z+i/2)}| = e^{A(y+1/2)} = e^{1/2A(|z_2|^2 - |z_1|^2)}$$

Thus we see that $|\sigma(z)| \exp(-\frac{1}{2}A|z|^2)$ is invariant, if z is increased by a primitive period and so by any period.

If $z = z_1$ is an arbitrary point in the plane we can always choose $z_2 = x_2 + iy_2$, so that $|x_2| \leq \frac{1}{2}, |y_2| \leq \frac{1}{2}$. Then $|z_2|$ is the distance from z to the nearest zero of $\sigma(z)$, and if we denote this distance by d , we see that there exist positive constants A_1, A_2 such that

$$A_1 d \leq |\sigma(z_2)| e^{-A|z_2|^2} \leq A_2 d.$$

Thus

$$A_1 d e^{1/2A|z|^2} \leq |\sigma(z)| \leq A_2 d e^{1/2A|z|^2},$$

where d is the distance from z to the nearest zero.

It is clear that $A > 0$, since otherwise $\sigma(z)$ would be constant by Liouville's Theorem.† Thus $\sigma(z)$ has order 2 mean type, and in fact

$$\log M(r) = \frac{A}{2} r^2 + O(1),$$

$$\log \mu(r) \sim \frac{A}{2} r^2,$$

$$N(r) \sim Ar^2.$$

For all values of z_0 on $|z_0| = r$ there is a zero in $|z - z_0| \leq 1/\sqrt{2}$, whereas Theorem 10 asserts that there is no such zero in

$$|z - z_0| \leq cr \{N(r) \log N(r)\}^{-1/2}$$

Thus the index $\frac{1}{2}$ in (3.4) and in the corresponding estimate for τ in (6.5) cannot be replaced by any smaller quantity.

† In fact an application of Jensen's formula shows at once that $A = \pi/2$.

Theorem 10 also shows that if $|f(z_0)| > \eta \exp(\frac{1}{2}Ar^2)$ then $f(z)$ has an asymptotic formula and so $f(z) \neq 0$ for $|z - z_0| < c\eta/(\log r)^{1/2}$, where c is a constant. This gives the right result apart from the factor $(\log r)^{-1/2}$. Clunie [4, 5] had stated Theorems of the type of Theorem 10 but with $|\tau| \leq A/k$ instead of $|\tau| \leq \eta/(30k)$, where A is a constant. The above examples show that no Theorem of this kind can be true. However Clunie's argument correctly yields Theorem 10 for functions of finite order.

To see the size that η may take in Theorem 10 for this example we investigate the minimum modulus of $\sigma(z)$, or what is the same thing, the distance of an arbitrary circle $|z|=r \geq 1$ to the nearest lattice point. Given r , let x be the fractional part of r^2 . Then if $z = m + in$ is any zero $|r^2 - |z|^2| \geq \min(x, 1 - x)$, so that for most r , $(r - |z|) \geq c/r$ for all zeros, where c is a positive constant and so $\eta \geq c^2 N(r)^{-1/2}$ in Theorem 10. On the other hand if we choose for m the largest integer, such that $m^2 \leq r^2$, and then for n the largest integer such that $m^2 + n^2 \leq r^2$, we see that

$$r^2 - m^2 \leq 2m + 1 = O(r), \quad r^2 - m^2 - n^2 \leq 2n + 1 = O(r^{1/2}),$$

so that if $z = m + in$, $(r - |z|) = O(r^{-1/2})$. Thus we can always find a point on $|z|=r$, where

$$f(z) = O\{M(r, f)r^{-1/2}\} = O\{M(r, f)N(r)^{-1/4}\}.$$

Thus η can take any value between $cN(r)^{-1/4}$ and 1, for any positive r , and for any such η , the estimate for the disk in which an asymptotic expansion holds, is sharp, apart from a possible factor $(\log r)^{-1/2}$.

7.1. How large must k and η be? Another example. It is natural to ask whether the factor $\{-\log b(N)\}^{1/2}$ which occurs in the definition of k in (3.4) and so in (6.5) is really necessary. We proceed to give an example to show that this is the case.

For this purpose we set

$$(7.1) \quad \alpha'(t) = -\frac{2}{t}, \quad t \geq 1, \quad \alpha'(t) = -2, \quad t \leq 1$$

in the construction of section 2, and then, with a suitable choice of K we have

$$(7.2) \quad \alpha(t) = -2(\log t + 1), \quad t \geq 1, \quad \rho_n = e^2 n^2, \quad \alpha_n = n^{-2n}, \quad n \geq 1,$$

in (2.1), and $b(N) = 2/N$. We now set

$$(7.3) \quad \phi_1(z) = \sum' \alpha_n z^n, \quad \phi_2(z) = \sum_0^\infty \alpha_n z^n$$

where the sum \sum' is taken over certain indices which will now be described. We define a sequence λ_ν inductively by

$$(7.4) \quad \lambda_{\nu+1} = \lambda_\nu + [\frac{1}{2}(\lambda_\nu \log \lambda_\nu)^{1/2}], \quad \nu \geq 1, \quad \lambda_1 = 4,$$

where $[x]$ denotes the integral part of x . We then sum \sum' in (7.3) over all those powers n for which, for some $\nu \geq 1$, we have

$$\lambda_\nu \leq n \leq \lambda_\nu + \frac{1}{4}\lambda_\nu^{1/2}, \quad \text{or } n = \lambda_\nu \mp [\varepsilon(\lambda_\nu \log \lambda_\nu)^{1/2}],$$

where ε is a positive constant, which we take to be small. We write

$$d_\nu = [\varepsilon(\lambda_\nu \log \lambda_\nu)^{1/2}], \quad \lambda'_\nu = \lambda_\nu + d_\nu, \quad \lambda''_\nu = \lambda_{\nu+1} - d_{\nu+1}.$$

Then it follows from the analysis of section 1.2 that, for

$$(7.5) \quad e^2\lambda_\nu'^2 \leq r \leq e^2\lambda_\nu''^2,$$

the central index $N_1(r)$ of $\phi_1(z)$ is either λ'_ν or λ''_ν . Also, if $\mu_1(r), \mu_2(r)$ are the maximum terms of $\phi_1(z), \phi_2(z)$, then $\mu_1(r) \leq \mu_2(r)$. Further if r lies in the range (7.5) then the central index $N_2(r)$ of $\phi_2(z)$ satisfies

$$(7.6) \quad \lambda'_\nu \leq N_2(r) \leq \lambda''_\nu.$$

Now the analysis of section 2 shows that if

$$(7.7) \quad \lambda_\nu \leq n \leq \lambda_\nu + \frac{1}{4}\lambda_\nu^{1/2},$$

and r lies in the range (7.5) so that $N_2(r)$ satisfies (7.6) we have

$$\frac{\alpha_n r^n}{\mu_2(r)} = \exp\left\{- (1+o(1)) \frac{(n-N)^2}{N}\right\},$$

where $N=N_2(r)$. Thus if we sum over the range (7.7) and r is sufficiently large, we deduce that

$$\frac{\sum \alpha_n r^n}{\mu_2(r)} > \frac{\lambda_\nu^{1/2}}{4} \exp\left\{-\frac{6k^2}{5N}\right\}$$

where $k=N-\lambda_\nu$. Thus

$$\begin{aligned} \frac{\sum \alpha_n r^n}{\mu(r)} &> \frac{\lambda_\nu^{1/2}}{4} \exp\left\{\frac{-5(\lambda_{\nu+1}-\lambda_\nu)^2}{4\lambda_\nu}\right\} \\ &> \frac{\lambda_\nu^{1/2}}{4} \exp\left\{\frac{-5 \log \lambda_\nu}{16}\right\} > \lambda_\nu^{1/6}, \end{aligned}$$

when ν is large. Thus for r in the range (7.5), we see that the terms in the range (7.7) are much larger than $\mu_2(r)$ and a fortiori than $\mu_1(r)$.

A similar analysis holds for the range (7.7) with ν replaced by $\nu+1$. The sum of these terms is also much larger than $\mu_2(r)$. On the other hand the remaining terms of $\phi_1(z)$ can be shown to be small compared with these so that for r in the range (7.5) we have

$$(7.8) \quad (1+o(1))\phi_1(r) = \sum_1 \alpha_n r^n + \sum_2 \alpha_n r^n,$$

where in \sum_1 we sum over the n satisfying (7.7), while in \sum_2 we sum over the n satisfying (7.7), with $(\nu+1)$ instead of ν . The indices in \sum_1 and \sum_2 satisfy respectively

$$n \leq N(r) - \frac{\varepsilon}{2} N(r)^{1/2} \log N(r)^{1/2}, \quad n \geq N(r) + \frac{\varepsilon}{2} N(r)^{1/2} (\log N(r)^{1/2}).$$

Thus for r satisfying (7.5) we cannot neglect both these ranges of terms in computing $\phi_1(r)$. Also the logarithmic density of all the ranges (7.5) is

$$\lim_{v \rightarrow \infty} \frac{\log(e^2 \lambda_v^{2^2}) - \log(e^2 \lambda_v^2)}{\log(e^2 \lambda_{v+1}^2) - \log(e^2 \lambda_v^2)} = \lim_{v \rightarrow \infty} \frac{(1-4\varepsilon)\lambda_v^{3/2} \log \lambda_v}{\lambda_v^{3/2} \log \lambda_v} = 1-4\varepsilon.$$

This can be chosen as near 1 as we please, by choosing ε small enough. Thus Lemma 2 fails if $\gamma_1=1$, and γ is sufficiently small.

Clearly $\phi_z(z)$ always attains its maximum modulus on the positive real axis. It is not difficult to see that if Σ_1, Σ_2 are defined as in (7.8) then in the range (7.5) we have for $z=re^{i\tau}$

$$\Sigma_1 \alpha_n z^n = e^{i\lambda_n \tau} (1 + o(1)) \Sigma_1 \alpha_n r^n,$$

if $\tau = o(\lambda_n^{-1/2})$, while

$$\Sigma_2 \alpha_n z^n = e^{i\lambda_{n+1} \tau} (1 + o(1)) \Sigma_2 \alpha_n r^n.$$

Thus provided that one of these sets of terms dominates the other a formula of the type given in (6.6) holds, but with λ_n or λ_{n+1} instead of $N(r)$. The difference is significant unless $(\lambda_{n+1} - \lambda_n)\tau \rightarrow 0$, i.e. unless $\tau = o\{N \log N\}^{-1/2}$, which is the order of magnitude for k^{-1} implied by (3.4) in this case. This limitation for the validity of (6.6) is therefore sharp, when $\eta=1$ in Theorem 10.

8. Maximum and minimum of the real part. We finish the paper by investigating the functions $A(r)$ and $B(r)$ of (1.4) in their relation to the maximum modulus $M(r)$. The following classical result is an immediate consequence of Theorem 10.

THEOREM 14 [Wiman, 23]. *If $f(z)$ is a transcendental integral function and $A(r), B(r), M(r)$ are defined by (1.4) and (1.2) respectively then we have*

$$(8.1) \quad -A(r) \sim B(r) \sim M(r)$$

as $r \rightarrow \infty$ outside an exceptional set of finite logarithmic measures.

We apply Theorem 10 with $\eta=1$ taking $b(N) = \{N(\log N)^2\}^{-1}, k = N^{1/2}(\log N)^{3/2}$. Then (6.6) yields for $|\tau| \leq 2\pi N^{-1}, z = z_0 e^\tau$

$$\log \frac{f(z)}{f(z_0)} = N\tau + \frac{O(\log N)^{3/2}}{N^{1/2}}.$$

Suppose that z_0 is chosen so that $f(z_0) = M \exp(i\lambda)$, where $M = M(r, f)$ and $-\pi \leq \lambda < \pi$. We choose $\tau = -i\lambda/N$ and obtain for $z = z_0 \exp(i\tau)$

$$\log f(z) = \log M + o(1),$$

so that

$$f(z) = u(z) + iv(z) = (1 + o(1))M$$

and hence

$$B(r) \geq (1 + o(1))M.$$

Similarly by choosing $\tau = i(\pi - \lambda)/N$, we obtain for $z = z_0 e^\tau$

$$\log f(z) = (-1 + o(1))M$$

so that

$$A(r) \leq (-1 + o(1))M.$$

Since clearly $|A(r)| \leq M$, $B(r) \leq M$, we obtain (8.1). Also in view of Theorem 2 we see that the exceptional set of r has finite logarithmic measure. This proves Theorem 14.

If we are prepared to admit a larger exceptional set we can obtain a much more precise result. This is

THEOREM 15.† *Suppose that $f(z)$ is a transcendental integral function and set*

$$(8.2) \quad \overline{\lim}_{r \rightarrow \infty} \frac{\log \log M(r)}{\log \log r} = p.$$

Then given $\varepsilon > 0$, we have on a set of r of positive upper logarithmic density

$$(8.3) \quad B(r) > M(r) \left(1 - \frac{\pi^2(\alpha(p) + \varepsilon)}{2 \log M(r)}\right), \quad -A(r) > M(r) \left(1 - \frac{\pi^2(\alpha(p) + \varepsilon)}{2 \log M(r)}\right)$$

where $\alpha(p) = 0$ if $p < 2$, $\alpha(p) = (p - 1)/p$, if $2 \leq p < \infty$, $\alpha(p) = 1$ if $p = \infty$.

In the opposite direction we have

THEOREM 16.† *For any p , such that $2 \leq p \leq \infty$, there exists $f(z)$ satisfying (8.2) and such that we have as $r \rightarrow \infty$*

$$B(r) = M(r), \quad -A(r) = M(r) \left(1 - \frac{\pi^2(\alpha(p) + o(1))}{2 \log M(r)}\right).$$

Clearly by considering $-f(z)$ instead of $f(z)$ we obtain a corresponding example with $-A(r)$ and $B(r)$ interchanged.

8.1. Proof of Theorem 15: preliminaries. We apply the preceding theory with

$$b(N)^{-1} = N(\log N)^2, \quad k = N^{1/2}(\log N)^{3/2}.$$

Then the set of exceptional r has finite logarithmic measure and if r is normal, and if $|z_0| = r$, $f(z_0) = M \exp(i\lambda)$, $M = M(r, f)$, Theorem 11 yields

$$\log f(z_0 e^{i\theta}) = \log M + i(\lambda + \theta a(r)) - \frac{1}{2} \phi_2 \theta^2 + O\{|\theta|^3 N(r)^{3/2 + \delta}\}$$

for every positive δ and $|\theta| = o(k^{-1})$. By comparing Theorems 10 and 11 we also deduce that

$$N(r) \sim a(r) \quad \text{as } r \rightarrow \infty \text{ for normal values.}$$

We now choose $\theta = h/a(r)$, where $|h| \leq \pi$. Then the above asymptotic formula certainly yields

$$\log f(z_0 e^{i\theta}) = \log M + i(\lambda + h) - \phi_2 \frac{h^2}{a(r)^2} + O(a(r)^{-3/2 + \delta}).$$

† Not previously published.

We may suppose that $|\lambda| \leq \pi$. Then if we choose $h = -\lambda$, we obtain

$$\log f(z_0 e^{i\theta}) = \log M - \phi_2 \frac{h^2}{a(r)^2} + O(a(r)^{-3/2+\delta}).$$

Thus if $f(z_0 e^{i\theta}) = u + iv$

$$u + iv = M \exp\left\{-\phi_2 \frac{h^2}{a(r)^2} + O(a(r)^{-3/2+\delta})\right\},$$

so that

$$\begin{aligned} (8.4) \quad B(r) \geq u(z) &\geq M \left\{ 1 - \frac{(1+o(1))\pi^2 |\phi_2|}{a(r)^2} + O(a(r)^{-3/2+\delta}) \right\} \\ &\geq M \left\{ 1 - \frac{(1+o(1))\pi^2 b(r)}{2a(r)^2} + O(a(r)^{-3/2+\delta}) \right\} \end{aligned}$$

in view of Theorem 11. By choosing $h = \pi - \lambda$, if $\lambda > 0$ and $h = -\pi - \lambda$ if $\lambda < 0$, we obtain a similar inequality for $-A(r)$.

To complete the proof we proceed to estimate the quantities occurring in (8.4). We have first

LEMMA 9. *Let $f(x)$ be a positive increasing and convex function of x for $x \geq x_0$ and suppose that*

$$(8.5) \quad \lim_{x \rightarrow \infty} \frac{\log f(x)}{\log x} \leq p \leq \overline{\lim}_{x \rightarrow \infty} \frac{\log f(x)}{\log x}, \quad \text{where } p > 1.$$

Let $\alpha(p) = (p-1)/p$ if $p < \infty$; $\alpha(p) = 1$, if $p = \infty$. Suppose that a, K are constants such that $K > 1$, and $a < \alpha(p)$. Then if E is the set of all x such that†

$$\frac{f(x)f''(x)}{f'(x)^2} \leq K\alpha(p), \quad \text{and } f'(x) > f(x)^a,$$

we have $\overline{\text{dens}} E \geq (K-1)/K$.

Suppose first that p is finite. Then we choose p_1, p_2 such that $p_1 < p < p_2$ and $\alpha(p_1) > a$. Then by hypothesis we can choose x_1 as large as we please such that

$$(8.6) \quad f(x_1) > x_1^{p_1}.$$

Let C be a large positive constant and suppose that

$$(8.7) \quad \frac{f'(x)}{f(x)} > \frac{p_2}{x}, \quad \text{for } Cx_1 < x < x_2.$$

Then we deduce that

$$(8.8) \quad f(x_2) \geq f(Cx_1) \left(\frac{x_2}{Cx_1}\right)^{p_2} \geq C^{-p_2} x_1^{p_1} \left(\frac{x_2}{x_1}\right)^{p_2}.$$

† Since $f(x)$ is convex, $f''(x)$ exists almost everywhere. We define $f'(x)$ to be the right derivative of $f(x)$, so that $f'(x)$ is increasing for all $x \geq x_0$ and continuous outside a countable set.

In view of (8.5) this inequality must be false for some arbitrary large x_2 . Thus we choose x_2 maximal subject to (8.7), and deduce that

$$(8.9) \quad \frac{f'(x_2)}{f(x_2)} \leq \frac{p_2}{x_2}, \quad x_2 \geq Cx_1,$$

and also that we have

$$(8.10) \quad f(x) \geq C^{-p_2}x^{p_1}, \quad x_1 \leq x \leq x_2.$$

We next note that $f'(x)$ increases so that

$$f(x) = f(x_0) + \int_{x_0}^x f'(t) dt \leq f(x_0) + (x - x_0)f'(x) \leq 2xf'(x)$$

when x is large enough. Thus we deduce from (8.10) that

$$f'(x) \geq \frac{f(x)}{2x} \geq f(x) \frac{1}{2} \left(\frac{C^{-p_2}}{f(x)} \right)^{1/p_1} > f(x)^a, \quad x_1 \leq x \leq x_2$$

provided that x_1 is large enough. Also (8.9) holds.

If p is infinite, we choose p_1 so that $\alpha(p_1) > a$. We may then still choose x_1 as large as we please to satisfy (8.6) and in this case we set $x_2 = Cx_1$ and deduce that

$$f(x) \geq x_1^{p_1} \geq C^{-p_1}x^{p_1}, \quad x_1 \leq x \leq x_2,$$

and this in turn leads to

$$(8.11) \quad f'(x) > f(x)^a, \quad x_1 \leq x \leq x_2.$$

Thus we deduce that in all cases we can find x_1 as large as we please and $x_2 \geq Cx_1$ such that (8.11) holds and in addition (8.9) holds if p is finite with any $p_2 > p$.

We now note that if

$$\phi(x) = x - \frac{f(x)}{f'(x)}, \quad \text{then } \phi'(x) = \frac{f(x)f''(x)}{f'(x)^2}$$

almost everywhere. Also for $x \geq x_0, h > 0$, we have, since $f'(t)$ increases

$$\frac{f(x+h)}{f'(x+h)} = \frac{f(x) + \int_x^{x+h} f'(t) dt}{f'(x+h)} \leq \frac{f(x) + hf'(x+h)}{f'(x+h)} \leq \frac{f(x)}{f'(x)} + h.$$

Thus $\phi(x)$ is non-decreasing. Suppose now that E_1 is the subset of $[x_1, x_2]$ in E and let E_2 be the rest of the interval $[x_1, x_2]$. Then we have almost everywhere in E_2

$$\phi'(x) = \frac{f(x)f''(x)}{f'(x)^2} > K\alpha(p)$$

since (8.11) holds in E_2 . Since $\phi(x)$ increases with x we deduce that

$$\phi(x_2) - \phi(x_0) \geq \int_{x_0}^{x_2} \phi'(t) dt \geq \int_{E_2} \phi'(t) dt \geq K\alpha(p)m(E_2),$$

so that

$$m(E_2) \leq \frac{\phi(x_2) - \phi(x_0)}{K\alpha(p)}.$$

If $p = \infty$, this gives

$$(8.12) \quad m(E_2) \leq \frac{x_2}{K} + O(1).$$

If $p < \infty$, we may apply (8.9) and deduce that

$$\phi(x_2) \leq \left(1 - \frac{1}{p_2}\right)x_2 = \alpha(p_2)x_2.$$

Thus in this case we deduce that

$$m(E_2) \leq \frac{\alpha(p_2)}{K\alpha(p)}x_2 + O(1).$$

Thus we have in this case

$$m(E_1) = (x_2 - x_1) - m(E_2) \geq x_2 \left(1 - \frac{\alpha(p_2)}{K\alpha(p)} - \frac{1}{C} + \frac{O(1)}{x_2}\right).$$

This is true for some arbitrary large x_2 and hence

$$\overline{\text{dens}} E \geq 1 - \frac{\alpha(p_2)}{K\alpha(p)} - \frac{1}{C}.$$

Since we may choose C as large as we please and p_2 as near p as we please we deduce that $\overline{\text{dens}} E \geq 1 - K^{-1}$. The same conclusion follows from (8.12) if $p = \infty$, and this completes the proof of Lemma 9.

8.2 Completion of the proof of Theorem 15. We suppose first that $p > 3$ in (8.2). In this case we set $r = e^x$, and apply Lemma 9 with

$$f(x) = \log M(e^x), \quad f'(x) = a(e^x), \quad f''(x) = b(e^x),$$

choose a so that $\frac{2}{3} < a < 1 - 1/p$ and let E be the set of r for which

$$\frac{b(r)\log M(r)}{a(r)^2} \leq K\alpha(p) \quad \text{and} \quad a(r) > (\log M(r))^a.$$

Then, by Lemma 9, E has upper logarithmic density at least $1 - K^{-1}$. Also for normal r on E we have, in view of (8.4),

$$(8.13) \quad B(r) \geq M(r) \left(1 - \frac{K\pi^2\alpha(p)}{2 \log M(r)} + \frac{o(1)}{\log M(r)}\right)$$

provided that δ is chosen so small that $((3/2) - \delta)a > 1$. Given $K_1 > K$, we deduce that

$$B(r) \geq M(r) \left(1 - \frac{K_1\pi^2\alpha(p)}{\log M(r)}\right)$$

on a set of upper logarithmic density at least $1 - 1/K$. Since we may choose K as near K_1 as we please, Theorem 15 follows.

Suppose now that $2 \leq p \leq 3$. Then we may apply Theorems 10, 11 as before but now we can use the better estimate for k and hence τ , which follows from Theorem 4, with any $p_1 > 3$ and $\delta = 0$. In particular we may choose $b(N) \geq N^{-1/2-\delta}$, for any $\delta > 0$, and so $k < N^{1/4+\delta}$ for any $\delta > 0$. When we apply this to Theorem 10 we see that we obtain the improved error term

$$\delta(\tau) = O(\tau^3 N^{3/4+3\delta}) = O\{N^{-9/4+3\delta}\} = O(a(r)^{-9/4+3\delta})$$

in (8.4). We can now apply Lemma 9 again, but with a so chosen that $a < \frac{1}{2}$, $9a/4 > 1$, and we again obtain (8.13). Since the set of non-normal r has zero logarithmic density the conclusion again holds on a set of upper logarithmic density at least $(K-1)/K$.

Finally suppose that $1 \leq p < 2$. In this case we apply Lemma 4. We suppose that r is a quantity satisfying the conditions of that Lemma with some $\eta < 2-p$, and deduce that

$$M(r) < \mu(r)\{1 + \exp(-(\log r)^\eta)\}.$$

We also choose θ so that if $z = re^{i\theta}$ then $a_N z^N$ is real and positive. Then

$$B(r) \geq a_N z^N - \sum_{n \neq N} |a_n z^n| \geq \mu(r)\{1 - \exp(-(\log r)^\eta)\}.$$

Thus if r is large

$$M(r) - B(r) < 2\mu(r)\exp(-(\log r)^\eta) \leq 2M(r)\exp\{-\log M(r)^{\eta'/p}\},$$

for any $\eta' < \eta$, and this result is stronger than (8.13). This completes the proof of Theorem 15.

8.3. Proof of Theorem 16. We proceed to construct our examples. Suppose first that $p = \infty$. In this case we set $f(z) = e^z$. We have for $z = re^{i\theta}$

$$u = \exp(r \cos \theta) \cos\{r \sin \theta\}.$$

Choose $\theta = \delta/r$, where $|\delta| \leq \pi$. Then we have uniformly for θ in this range as $r \rightarrow \infty$

$$u = e^r \left\{ 1 - \frac{\delta^2}{2r} + O(r^{-3}) \right\} \cos\{\delta + O(r^{-2})\}.$$

To make $-u$ as large as possible $|\delta|$ must be near to π . Thus we have throughout this range

$$(8.14) \quad -u \leq e^r \left(1 - \frac{\pi^2 + o(1)}{2r} \right),$$

and for $\pi/r \leq |\theta| \leq \pi$, we have evidently

$$-u \leq \exp(r \cos \theta) \leq \exp(r \cos \pi/r).$$

Thus (8.14) holds uniformly as $r \rightarrow \infty$ for $|\theta| \leq \pi$, and we deduce that

$$-A(r) \leq e^r \left(1 - \frac{\pi^2 + o(1)}{2r} \right) = M(r) \left\{ 1 - \frac{\pi^2 + o(1)}{2 \log M(r)} \right\}.$$

By taking $\theta = \pi/r$, we deduce that

$$-A(r) \geq \exp(r \cos \pi/r) = e^r \left(1 - \frac{\pi^2 + o(1)}{2r} \right).$$

Evidently $B(r) = M(r) = e^r$, so that Theorem 16 is proved in this case.

Suppose next that $2 \leq p < \infty$. In this case we set

$$f_p(z) = \prod_{n=1}^{\infty} \left(1 + \frac{z}{\rho_n} \right)$$

where

$$(8.15) \quad \rho_n = \exp\{n^{1/(p-1)}\}, \quad p > 2; \quad \rho_n = \exp\{n/\log n\}, \quad p = 2.$$

It is evident that $|f(re^{i\theta})|$ attains its maximum for given r when $\theta = 0$ and decreases steadily with increasing $|\theta|$ for $0 \leq |\theta| \leq \pi$. To obtain an estimate for $f(re^{i\theta})$ when θ is small, we proceed as follows. We write

$$b_p(z) = \left(z \frac{d}{dz} \right)^2 \log f_p(z) = \sum_{n=1}^{\infty} \frac{\rho_n z}{(z + \rho_n)^2}, \quad a_p(z) = z \frac{d}{dz} \log f(z).$$

Suppose first that $z = \rho_N$, and set $n = N + k$. Then for $p > 2$, $|k| \leq \frac{1}{2}N$

$$\frac{\rho_n}{\rho_N} = \exp\{(N+k)^{1/(p-1)} - N^{1/(p-1)}\} = \exp\left\{ \frac{kN^{(2-p)/(p-1)}}{p-1} + O(k^2 N^{(3-2p)/(p-1)}) \right\}.$$

We set

$$c_N = \frac{N^{(2-p)/(p-1)}}{p-1},$$

and deduce that for $k = o(N)$

$$\frac{\rho_n}{\rho_N} = \exp\{-kc_N(1 + o(1))\}.$$

This leads to

$$b_p(\rho_N) \sim \sum_{k=-\infty}^{+\infty} (e^{1/2kc_N} + e^{-1/2kc_N})^{-2} \sim \int_{-\infty}^{\infty} \frac{dx}{(e^{1/2c_N x} + e^{-1/2c_N x})^2} = \frac{1}{c_N}.$$

Since $\rho_n/\rho_{n+1} \rightarrow 1$, as $n \rightarrow \infty$, we deduce that for $\rho_n < \rho < \rho_{n+1}$

$$b_p(\rho) \sim b_p(\rho_n) \sim (p-1)n^{(p-2)/(p-1)} \sim (p-1)(\log \rho)^{p-2},$$

and integrating twice with respect to $\log r$ yields

$$a_p(\rho) \sim (\log \rho)^{p-1}, \quad \log f_p(\rho) \sim \frac{(\log \rho)^p}{p}.$$

It is not difficult to see that the above asymptotic expressions for $b_p(\rho)$, $a_p(\rho)$ and $\log f_p(\rho)$ remain valid when we set $\rho = z$, and allow z to be complex, provided that $|\arg z| < \pi - \delta$ for some positive δ . For instance a straightforward estimate shows that in this range

$$|b_p(z)| = O(\log |z|)^{p-2},$$

and now we can use Montel's theorem to show that

$$\frac{b_p(z)}{(\log z)^{p-2}} \rightarrow p-1, \text{ as } |z| \rightarrow \infty$$

uniformly for $|\arg z| < \pi - \delta$, for any fixed δ . From this we can deduce that for $|\tau| < \pi/2$, say and ρ real and positive, we have

$$\log f_p(\rho e^{i\tau}) = \log f_p(\rho) + i\tau a_p(\rho) - \frac{1}{2}\tau^2 b_p(\rho) + O(|\tau|^3 |b_p(\rho)|).$$

If we set $f_p(\rho e^{i\tau}) = u + iv$, this gives for τ real and $|\tau| |a_p(\rho)| \leq \pi$

$$u = f_p(\rho) \left(1 - \frac{1}{2}\tau^2 b_p(\rho) + O(|\tau|^3 |b_p(\rho)|) \right) \cos(\tau a_p(\rho) + O(|\tau|^3 |b_p(\rho)|)),$$

and we deduce that for u to have its minimum value in this range we must have $|\tau| |a_p(\rho)| \sim \pi$. Thus for $|\tau| \leq \pi/a_p(\rho)$

$$u \geq -f_p(\rho) \left[1 - \frac{\pi^2 b_p(\rho)}{2a_p(\rho)^2} (1 + o(1)) \right] = -f_p(\rho) \left(1 - \frac{(\pi^2 + o(1))(p-1)}{2p \log f_p(\rho)} \right);$$

for $\pi/a_p(\rho) \leq \theta \leq \pi$, we have

$$\begin{aligned} |u(\rho e^{i\theta})| &\leq |f_p(\rho e^{i\theta})| \leq |f_p\{\rho(\exp i\pi/a_p(\rho))\}| \\ &= f_p(\rho) \left(1 - \frac{(\pi^2 + o(1))(p-1)}{2p \log f_p(\rho)} \right). \end{aligned}$$

Thus we deduce that

$$\begin{aligned} A(r, u) &= -f_p\{\rho \exp(i\pi/a_p(\rho))\} + o\{f_p(\rho)/\log f_p(\rho)\} \\ &= -f_p(\rho) \left\{ 1 - \frac{(\pi^2 + o(1))\alpha(p)}{2 \log f_p(\rho)} \right\}. \end{aligned}$$

When $p=2$ the above argument has to be modified slightly, since an asymptotic formula for $b(\rho)$ only holds if $\rho_{n+1}/\rho_n \rightarrow 1$. We have

$$\rho_n = \exp(n/\log n)$$

from (8.15) and then the argument goes through essentially as before, with

$$c_N = \frac{1}{\log N}, \quad b_2(\rho_N) \sim \frac{1}{c_N} = \log N,$$

so that

$$\begin{aligned} b_2(\rho) &\sim \log \log \rho, & a_2(\rho) &\sim \log \rho \log \log \rho, \\ \log f_2(\rho) &\sim \frac{1}{2}(\log \rho)^2 \log \log \rho. \end{aligned}$$

We again deduce that if $A_2(r)$ is the minimum of the real part of $f_2(z)$, then

$$\begin{aligned} -A_2(r) &= f_2(r) \left(1 - \frac{\pi^2(1+o(1))b_2(r)}{2a_2(r)^2} \right) \\ &= f_2(r) \left(1 - \frac{\pi^2+o(1)}{4 \log f_2(r)} \right) \end{aligned}$$

so that Theorem 16 holds when $p=2$. This completes our proof.

9. Conclusion. The foregoing results represent some of the main achievements of Wiman-Valiron theory. Its development in the present form is due to many people, but the principal credit after the original authors is probably due to Clunie [4, 5], who sharpened the form of the error term and also introduced the notion of density in connection with the theory, as it occurs for instance in Theorem 3, and to Kövari [11], who developed the very nice form of comparison sequences in section 2. This has made the basic theory much less formidable than it used to be.

A number of developments have been left out. For instance Theorem 5 lends almost immediately to a relation between the maximum modulus and characteristic of functions with Picard values [cf. 9]. Another subject to which the theory has been successfully applied is that of power series with gaps [see e.g. 6, 10, 11, 16]. However it seems to me that many of the latter applications, which deal with terms well away from the central index, can be obtained by means of more elementary methods, such as Cauchy's inequality combined with growth Lemmas similar to Lemma 1.

The theory as it stands seems dependent on upper growth, since in the development of section 1.2 the comparison sequences α_n have to be larger than $|a_n|$ for all n . Recently this disadvantage of the theory has to some extent been overcome by Sons [16] who has obtained results for functions of finite lower order but without conclusions about density. Some extensions of this general nature would seem to be desirable in order to replace upper logarithmic density by lower logarithmic density or alternatively to replace the upper limit by the lower limit in the statement of Theorem 15.

The Wiman-Valiron theory can be extended to functions in the unit disk (see e.g. [12]) but Kövari feels that the probabilistic technique of Rosenbloom [14] is generally more successful here.

I am most grateful to the referee for carefully reading through the whole of this paper and correcting some errors.
