

The opium poppy in Europe: exploring its origin and dispersal during the Neolithic

Aurélie Salavert^{1,*}, Lucie Martin², Ferran Antolín³ & Antoine Zazzo¹

A new project aims to define the origins and dispersal patterns of the opium poppy in Neolithic Western Europe through a comprehensive programme of radiocarbon dating.

Introduction

The opium poppy (*Papaver somniferum* L.) has been of economic, therapeutic and symbolic importance for thousands of years, as evidenced by reference to opium production in fourth-millennium BC Sumerian clay tablets (Kritikos & Papadaki 1967). In the absence of historical sources, archaeological seeds (and, only rarely, capsules and stigmatic disks) constitute the most direct and reliable evidence of the presence, use and cultivation of opium poppies in the past (Figure 1).

It is hypothesised that opium poppies were originally cultivated in the Mediterranean basin from the middle of the sixth millennium BC, where its putative wild ancestor—*Papaver somniferum* subsp. *setigerum*—developed (Hammer & Fritsch 1979; Schultze-Motel 1979). To date, however, the most frequent discoveries of *Papaver somniferum* beyond the Mediterranean region are from Linear Pottery Culture sites (5300–4900 BC); it thus followed a dispersal pattern from south to north (Bakels 1996; Salavert 2011) (Figure 2). The opium poppy is found in the Alpine region by the beginning of the fifth millennium BC (Martin 2015). This distribution raises the question of the diffusion process and the status of the plant. Why was it so rapidly adopted by Early Neolithic farmers in the north of continental Europe and the Alps at the end of the sixth millennium BC? Opium poppies do not seem to have followed the same dispersal trajectories as the cereals and pulses that accompanied the first farmers from the Near East to Western Europe, where the earliest finds of poppies, dating from 5300 BC onwards, are concentrated (Salavert 2010, 2017; Antolín *et al.* 2015). The opium poppy, therefore, may be the only plant whose domestication process began in Neolithic Europe.

Several obstacles currently prevent us from progressing the study of ancient poppy cultivation. The chronological framework covering the origins and distribution of the opium poppy is somewhat imprecise, being based on indirect and low-resolution dates. In addition, the native distribution area and the wild ancestor of the cultivated opium poppy are not identified with certainty; this strongly limits the hypotheses about the location of its early cultivation. Furthermore, the first uses and socio-economic status of the plant have been difficult to define due to their sparse representation in the archaeological record.

Aims of the project and methodology

This one-year project aims to reveal the origin of the opium poppy as a cultivar, and its spread across other regions, by providing a solid chronological framework. We will perform AMS dating of seeds from annual plants recovered from the same sieves as poppy seeds at approximately 40 Neolithic reference sites. Poppy seeds will also be directly dated, although low sample weight (typically 10–30 μ g per seed) presents a challenge. To overcome this, we will use the mini radiocarbon dating system installed at Gif-sur-Yvette in France (ECHO-MICADAS), which allows for analysis of very small samples (Figure 3). The results will then

be analysed using a geographic information system (open-source software, QGIS[®]), in order to identify the potential cradle(s), rhythms and diffusion processes of the opium poppy in Neolithic Western Europe. The project also aims to create a European interdisciplinary network to study the history of the opium poppy over a longer period of time and larger geographic area (Figure 4).

Acknowledgements

This project 'Origine et premières diffusions du pavot somnifère en Europe au Néolithique' has received a research grant from the Fyssen Foundation. We would like to thank the following colleagues for their helpful advice and for providing seeds to the radiocarbon programme: C. Bakels, A. Bienek, N. Bleicher, E. Bonnaire, L. Bouby, C. Bouchaud, C. Brombacher, L. Castelletti, P.-A. Chouvy, I. Vostrovska, F. Jabbour, P. Marinval, R. Nisbet, M. Rottoli, N. Rovira, A. Schlumbaum, F. Toulemonde, O. Tombret, A. de Vareilles-Sommières, A. Jesus, R. Soteras and A. Fortó. We also acknowledge the GDRE Bioarch and the SNSF Professorship funding (PP00P1_170515) for the biometric analyses of poppy seeds (coordination: F. Antolín).
