Mental Hospital Kromeriz, Kromeriz, Czech Republic

Introduction: Differentiating Lewy Body Disease from dementia of Alzheimer's type might be difficult in clinical practice. Although the clinical signs in both categories are well known, difficulties may occur in patients with incomplete clinical picture.

Objectives and aims: Description of the case with incomplete clinical picture (women with unspecified dementia) and benefit of the DatCAN in differential diagnosis of clinically unclear dementia.

Methods: Case report.

Results: DatCAN helped in differential diagnosis of unspecified dementia. As the clinical picture of the case was incomplete and clinical diagnosis could not be done according diagnostic criteria, DatSCAN proved benefit in diagnostics of Lewy Body Disease.
