

Results: We found that the experiential domain correlated with the RS-FC of the VTA with the left ventro-lateral prefrontal cortex (IVLPFC) ($r=0.372$, $p=0.039$), while the Expressive deficit domain correlated with the RS-FC of the VTA with the left dorso-lateral prefrontal cortex (IDLFPFC) ($r=0.470$, $p=.008$). Looking at subdomains, only the avolition ($r=0.418$, $p=0.019$) and the blunted affect ($r=0.465$, $p=.008$) showed the same correlations of the domains to which they belong.

Conclusions: According to our findings, separate dysfunctional neuronal circuits could underpin distinct negative symptom subdomains. A better understanding of neurobiological dysfunctions underlying NS could help to design new treatments, targeting different NS subdomains.

Introduction: Acute and transient psychotic disorders are a rare condition entity as the sudden appearance of affective, confusional symptoms and paranoia triggered by some psychological trauma. The current pandemic caused by COVID-19 is an important psychological stressor that could favor the appearance of acute psychotic disorders. Several studies have been recently published proposing that the multifactorial stress associated with lockdown could function as a catalyst for acute psychotic disorders.

Objectives: To present a case of a brief psychotic disorder during the national lockdown in Spain and to review the literature about the relationship between the current pandemic and psychosis.

Methods: We will present a case report and a literature review.

Results: We report a case of a 27-year-old woman, with no previous psychiatric history. Three weeks after the start of Spain lockdown sudden symptoms appeared with psychomotor restlessness, confused speech, emotional lability, thought blocking and persecutory and referential delusions. Physical exam, blood analysis and cerebral CT scan with no alterations. Treatment was performed with aripiprazole 10 mg and lorazepam 1 mg daily with clinical improvement in one week. She was diagnosed of Acute transient psychotic disorder.

Conclusions: Stressful life events that can trigger psychosis in vulnerable individuals and the current pandemic and lockdown context could favor the appearance of acute psychotic disorders. The case reported here is in line with other current studies that show a preliminary intuition of this trend.

doi: 10.1192/j.eurpsy.2021.1449

Introduction: Approximately, 15- 26% of patients with first-episode psychosis, including schizophrenia, are likely to have attempted suicide by their first treatment contact. Studies of suicidal behavior outside of schizophrenia have indicated grey matter volume loss in the prefrontal and orbitofrontal cortex, and aberrant brain activity in relation to emotional recognition and dysfunction.

Objectives: This study aimed to investigate the functional neural correlates of suicidal behavior in early schizophrenia.

Methods: fMRI faces task was conducted (fearful face versus neutral face) in 8 participants with first-episode schizophrenia together with standardised scales including PANSS and SBQ-R. fMRI activation was compared using a two-sample t-test in participants with low and high suicidal behavior. Extent threshold is 0 voxels and significance level $p<0.001$ (FWE corrected). Processing of images was carried out using SPM12 and Matlab.

Results: 8 participants were recruited; 5 males and 3 females, mean age of 26.5. Results suggest that participants with higher suicidal behaviour showed reduced activation on the anterior-cingulate gyrus and medial frontal gyrus, which are parts of PFC, ($p=.005$). There was also a significant difference in task response accuracy, where, participants with high suicidal behaviour made more accurate responses compared to low group ($t(3) = 3.65$, $p = .035$).

Conclusions: This is an exploratory study, investigated the differences in brain activity in patients with schizophrenia who are at risk of completed suicide and, therefore might provide new insights into the underlying mechanisms. Further work should address how PFC activity changes with risk over time and its potential utility as a biomarker in suicide.

Introduction: Memory and learning deficits are central among cognitive deficits in schizophrenia. However, to a varying proportion ca. 20-25% of patients could not be considered deficit.
