The geometry of monotone operator splitting methods

Patrick L. Combettes[∗]

We propose a geometric framework to describe and analyse a wide array of operator splitting methods for solving monotone inclusion problems. The initial inclusion problem, which typically involves several operators combined through monotonicitypreserving operations, is seldom solvable in its original form. We embed it in an auxiliary space, where it is associated with a surrogate monotone inclusion problem with a more tractable structure and which allows for easy recovery of solutions to the initial problem. The surrogate problem is solved by successive projections onto half-spaces containing its solution set. The outer approximation half-spaces are constructed by using the individual operators present in the model separately. This geometric framework is shown to encompass traditional methods as well as state-ofthe-art asynchronous block-iterative algorithms, and its flexible structure provides a pattern to design new ones.

1. Introduction

Throughout, H is a real Hilbert space with scalar product $\langle \cdot | \cdot \rangle$ and $2^{\mathcal{H}}$ stands for the power set of H . Our main focus is on the following monotone inclusion problem.

Problem 1.1. Let $M: \mathcal{H} \to 2^{\mathcal{H}}$ be a monotone operator, that is,

$$
(\forall x \in \mathcal{H})(\forall y \in \mathcal{H})(\forall x^* \in Mx)(\forall y^* \in My) \quad \langle x - y | x^* - y^* \rangle \ge 0. \tag{1.1}
$$

The task is to find $x \in \mathcal{H}$ such that $0 \in Mx$.

Monotone inclusion problems are intimately linked to the birth of nonlinear analysis. They first appeared as powerful models to establish existence, uniqueness and stability results for various nonlinear problems [\(Browder](#page-130-0) [1968/1976,](#page-130-0) [Ghizzetti](#page-136-0) [1969,](#page-136-0) Kačurovskiĭ [1960,](#page-144-0) [Zarantonello](#page-144-0) 1960, [1971\)](#page-145-0). Over the past six decades, monotone inclusion models have penetrated almost all areas of mathematics and its applications. Nowadays, Problem [1.1](#page-1-1) models a broad range of equilibria in areas such as dynamical systems [\(Adly, Hantoute and Le](#page-126-2) [2017\)](#page-126-2), ill-posed problems [\(Alber and Ryazantseva](#page-126-3) [2006\)](#page-126-3), domain decomposition methods [\(Alduncin](#page-126-4) [2023,](#page-126-4) [Attouch, Briceño-Arias and Combettes](#page-127-0) [2016,](#page-127-0) [Attouch, Cabot, Frankel and](#page-127-1) [Peypouquet](#page-127-1) [2011\)](#page-127-1), circuit theory [\(Anderson Jr and Trapp](#page-126-5) [1976,](#page-126-5) [Chaffey and Sep](#page-131-0)[ulchre](#page-131-0) [2024,](#page-131-0) [Chaffey, Banert, Giselsson and Pates](#page-131-1) [2023](#page-131-1)*a*, [Chaffey, Forni and Sep](#page-131-2)[ulchre](#page-131-2) [2023](#page-131-2)*b*, [Goeleven](#page-136-1) [2017\)](#page-136-1), machine learning [\(Argyriou, Foygel and Srebro](#page-127-2) [2012,](#page-127-2) [Combettes, Salzo and Villa](#page-133-0) [2018,](#page-133-0) [Jenatton, Mairal, Obozinski and Bach](#page-137-1) [2011,](#page-137-1) [Vaiter, Peyré and Fadili](#page-143-0) [2018\)](#page-143-0), evolution equations [\(Attouch, Briceño-Arias](#page-127-3) [and Combettes](#page-127-3) [2010,](#page-127-3) [Brézis](#page-129-0) [1973,](#page-129-0) [Showalter](#page-142-0) [1997\)](#page-142-0), partial differential equations [\(Barbu](#page-127-4) [2010,](#page-127-4) [Brézis and Browder](#page-129-1) [1998,](#page-129-1) [Clason and Valkonen](#page-132-0) [2017,](#page-132-0) [Ghoussoub](#page-136-2) [2009,](#page-136-2) [Pascali and Sburlan](#page-140-0) [1978,](#page-140-0) [Showalter](#page-142-0) [1997,](#page-142-0) [Zeidler](#page-145-1) [1990\)](#page-145-1), signal processing [\(Beck and Teboulle](#page-128-0) [2010,](#page-128-0) [Combettes and Pesquet](#page-133-1) [2011,](#page-133-1) [Combettes and Wajs](#page-133-2) [2005,](#page-133-2) [Potter and Arun](#page-140-1) [1993\)](#page-140-1), image processing [\(Bednarczuk, Jezierska and Rutkowski](#page-128-1) [2018,](#page-128-1) [Chambolle and Pock](#page-131-3) [2016,](#page-131-3) [Combettes and Woodstock](#page-133-3) [2022,](#page-133-3) [Glowinski,](#page-136-3) [Osher and Yin](#page-136-3) [2016,](#page-136-3) [Pesquet, Repetti, Terris and Wiaux](#page-140-2) [2021\)](#page-140-2), game theory [\(Belgioioso, Nedich and Grammatico](#page-128-2) [2021,](#page-128-2) [Börgens and Kanzow](#page-129-2) [2021,](#page-129-2) [Briceño-](#page-129-3)[Arias and Combettes](#page-129-3) [2013,](#page-129-3) [Bùi and Combettes](#page-130-1) [2022](#page-130-1)*a*, [Cohen](#page-132-1) [1987,](#page-132-1) [Facchinei](#page-135-0) [and Pang](#page-135-0) [2003,](#page-135-0) [Facchinei, Fischer and Piccialli](#page-135-1) [2007,](#page-135-1) [Gautam, Sahu, Dixit and](#page-135-2) [Som](#page-135-2) [2021\)](#page-135-2), network flow problems [\(Bertsekas](#page-128-3) [1998,](#page-128-3) [Bùi](#page-130-2) [2022](#page-130-2)*a*, [Rockafellar](#page-141-0) [1984,](#page-141-0) [1995\)](#page-141-1), equilibrium theory [\(Briceño-Arias](#page-129-4) [2012,](#page-129-4) [Combettes and Hirstoaga](#page-132-2) [2005,](#page-132-2) [Moudafi and Théra](#page-139-0) [1999\)](#page-139-0), mean-field games [\(Briceño-Arias, Deride, López-Rivera](#page-130-3) [and Silva](#page-130-3) [2023,](#page-130-3) [Briceño-Arias, Kalise and Silva](#page-130-4) [2018\)](#page-130-4), control theory [\(Brogliato](#page-130-5) [and Tanwani](#page-130-5) [2020,](#page-130-5) [Brogliato, Lozano, Maschke and Egeland](#page-130-6) [2007,](#page-130-6) [Camlibel and](#page-131-4) [Schumacher](#page-131-4) [2016,](#page-131-4) [Doležal](#page-134-0) [1979](#page-134-0)*a*, [Singh, Weiss and Tucsnak](#page-142-1) [2022\)](#page-142-1), data science [\(Chan, Wang and Elgendy](#page-131-5) [2017,](#page-131-5) [Combettes and Pesquet](#page-133-4) [2021,](#page-133-4) [Wright and Recht](#page-144-1) [2022\)](#page-144-1), optimization [\(Combettes](#page-132-3) [2018,](#page-132-3) [Eckstein and Bertsekas](#page-134-1) [1992,](#page-134-1) [Gol'shtein](#page-136-4) [and Tret'yakov](#page-136-4) [1996,](#page-136-4) [Tseng](#page-143-1) [1990,](#page-143-1) [1991\)](#page-143-2), statistics [\(Combettes and Müller](#page-132-4) [2020,](#page-132-4) [Yan and Bien](#page-144-2) [2021\)](#page-144-2), neural networks [\(Combettes and Pesquet](#page-133-5) [2020,](#page-133-5) [Winston and](#page-144-3)

[Kolter](#page-144-3) [2020,](#page-144-3) [Yi and Ching](#page-144-4) [2020\)](#page-144-4), traffic equilibrium [\(Dafermos](#page-133-6) [1980,](#page-133-6) [Fukushima](#page-135-3) [1996\)](#page-135-3), systems theory [\(Desoer and Vidyasagar](#page-134-2) [1975,](#page-134-2) [Doležal](#page-134-3) [1979](#page-134-3)*b*), mechanics [\(Fortin and Glowinski](#page-135-4) [1983,](#page-135-4) [Mercier](#page-139-1) [1980\)](#page-139-1), optimal transportation [\(Papadakis,](#page-140-3) [Peyré and Oudet](#page-140-3) [2014\)](#page-140-3) and minimax theory [\(Rockafellar](#page-141-2) [1970](#page-141-2)*b*).

Early numerical solution methods to solve Problem [1.1](#page-1-1) can be found in [Antipin](#page-126-6) [\(1976\)](#page-126-6), [Bruck](#page-130-7) [\(1973,](#page-130-7) [1974\)](#page-130-8), [Korpelevič](#page-137-2) [\(1976\)](#page-137-2), [Lions](#page-138-0) [\(2010\)](#page-138-0), [Petryshyn](#page-140-4) [\(1966\)](#page-140-4), [Sibony](#page-142-2) [\(1970\)](#page-142-2), Vaĭnberg [\(1960,](#page-144-0) [1961\)](#page-143-4) and [Zarantonello](#page-144-0) (1960, [1964\)](#page-145-2). These methods are of the explicit Euler type, meaning that, at iteration n , the update x_{n+1} is determined by finding a point in Mx_n . An alternative method, which first appeared in [Lieutaud](#page-138-1) [\(1969](#page-138-1)*a*) and then in more detail in [Rockafellar](#page-141-3) [\(1976](#page-141-3)*b*), is the proximal point algorithm, where the update is obtained through the implicit relation $x_n - x_{n+1} \in Mx_{n+1}$. Such approaches have limited potential since they can be directly implemented only in specific situations. For instance, the Euler step methods of [Bruck](#page-130-7) [\(1973,](#page-130-7) [1974,](#page-130-8) [1975\)](#page-130-9) impose certain properties on M and asymptotically vanishing step sizes, which is detrimental to numerical stability and speed of convergence. On the other hand, the proximal point algorithm requires explicit expressions for the resolvent of M , which is seldom possible. In most problems, however, M has a complex structure and it is typically expressed in terms of monotonicity-preserving operations involving simpler operators. The principle governing *splitting methods* is to devise algorithms in which each of the elementary operators arising in the decomposition of M are used individually, hence breaking up Problem [1.1](#page-1-1) into tasks that are more manageable.

The first monotone operator splitting methods arose in the late 1970s and were motivated by applications in mechanics and partial differential equations [\(Fortin](#page-135-4) [and Glowinski](#page-135-4) [1983,](#page-135-4) [Glowinski and Le Tallec](#page-136-5) [1989,](#page-136-5) [Mercier](#page-139-1) [1980\)](#page-139-1). The three main algorithms that dominated the field were designed for problems in which

$$
M = A + B,\tag{1.2}
$$

where $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{H} \to 2^{\mathcal{H}}$ are maximally monotone: the forwardbackward method [\(Mercier](#page-139-2) [1979\)](#page-139-2), the Douglas–Rachford method [\(Lions and Mer](#page-138-2)[cier](#page-138-2) [1979\)](#page-138-2) and Tseng's forward–backward–forward method [\(Tseng](#page-143-5) [2000\)](#page-143-5). In recent years, the field of monotone operator splitting algorithms has benefited from a new impetus, fuelled by the emerging application areas mentioned above and their demand for solving efficiently increasingly complex large-dimensional problems. Thus, duality techniques have arisen to address composite models of the form

$$
M = A + L^* \circ B \circ L,\tag{1.3}
$$

where L is a linear operator from H to a Hilbert space G and $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{G} \to 2^{\mathcal{G}}$ are maximally monotone [\(Briceño-Arias and Combettes](#page-129-5) [2011\)](#page-129-5). These techniques have been further developed to devise splitting algorithms for the more structured model (Bot and Hendrich [2014,](#page-129-6) [Combettes and Pesquet](#page-133-7) [2012,](#page-133-7) Vũ [2013\)](#page-144-5)

$$
M = A + \sum_{k=1}^{p} L_k^* \circ (B_k^{-1} + D_k^{-1})^{-1} \circ L_k + C,
$$
 (1.4)

where each linear operator L_k maps H to a Hilbert space G_k , and the operators $A: \mathcal{H} \to 2^{\mathcal{H}}, B_k: \mathcal{G}_k \to 2^{\mathcal{G}_k}, D_k: \mathcal{G}_k \to 2^{\mathcal{G}_k}$ and $C: \mathcal{H} \to \mathcal{H}$ are maximally monotone. Splitting algorithms for models which are more finely structured than [\(1.4\)](#page-3-0) have also been proposed, as well as multivariate versions that capture coupled systems of monotone inclusions; see [Bùi and Combettes](#page-131-6) [\(2022](#page-131-6)*b*) and the references therein. On a different front, block-iterative algorithms, which allow for the activation of only a subgroup of operators present in the model at a given iteration, have also been developed [\(Bùi](#page-130-10) [2022](#page-130-10)*b*, [Bùi and Combettes](#page-131-6) [2022](#page-131-6)*b*, [Combettes and](#page-132-5) [Eckstein](#page-132-5) [2018,](#page-132-5) [Johnstone and Eckstein](#page-137-3) [2022\)](#page-137-3). At the same time, a multitude of splitting algorithms tailored to specific models have been elaborated. For instance, if $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{H} \to 2^{\mathcal{H}}$ are maximally monotone and $C: \mathcal{H} \to \mathcal{H}$ is cocoercive, splitting algorithms have been proposed in [Davis and Yin](#page-134-4) [\(2017\)](#page-134-4) and [Raguet](#page-141-4) [\(2019\)](#page-141-4) for the decomposition $M = A + B + C$, and in particular in [Briceño-](#page-130-11)[Arias and Davis](#page-130-11) [\(2018\)](#page-130-11) if $B: H \to H$ is Lipschitzian and in [Latafat and Patrinos](#page-137-4) [\(2017\)](#page-137-4) if $B: H \to H$ is linear and bounded.

Given the abundance of activity in monotone operator splitting techniques, it is important to identify general structures and principles, as well as possible bonds between algorithm design methodologies, in order not only to simplify and clarify the state of the art but also to facilitate the developments of new methods in the future. From the outset, fixed point theory has been a tool of choice to achieve this goal. For instance, it has played an important role in the analysis of the proximal point algorithm [\(Kryanev](#page-137-5) [1973,](#page-137-5) [Martinet](#page-139-3) [1972,](#page-139-3) [Rockafellar](#page-141-3) [1976](#page-141-3)*b*). [Combettes](#page-132-6) [\(2004\)](#page-132-6) showed that fixed point iterations of averaged operators provide a convenient framework to investigate the asymptotic behaviour of classical splitting algorithms such as the forward–backward, backward–backward, Douglas–Rachford and Peaceman–Rachford algorithms. Further applications of averaged operator iterations to design and analyse splitting methods can be found in [Briceño-Arias](#page-130-12) [and Roldán](#page-130-12) [\(2023\)](#page-130-12), [Chambolle and Pock](#page-131-3) [\(2016\)](#page-131-3), [Combettes and Glaudin](#page-132-7) [\(2017\)](#page-132-7), [Combettes and Pesquet](#page-133-4) [\(2021\)](#page-133-4), [Combettes and Yamada](#page-133-8) [\(2015\)](#page-133-8), [Condat, Kitahara,](#page-133-9) [Contreras and Hirabayashi](#page-133-9) [\(2023\)](#page-133-9), [Davis and Yin](#page-134-4) [\(2017\)](#page-134-4), [Raguet](#page-141-4) [\(2019\)](#page-141-4), [Raguet](#page-141-5) [and Landrieu](#page-141-5) [\(2015\)](#page-141-5), [Raguet, Fadili and Peyré](#page-141-6) [\(2013\)](#page-141-6), [Ryu, Taylor, Bergeling and](#page-142-3) [Giselsson](#page-142-3) [\(2020\)](#page-142-3) and [Xue](#page-144-6) [\(2023](#page-144-6)*b*). Fixed point modelling is also a central algorithmic development tool in recent works such as those of [Aragón-Artacho, Boţ](#page-126-7) [and Torregrosa-Belén](#page-126-7) [\(2023\)](#page-126-7), [Briceño-Arias and Davis](#page-130-11) [\(2018\)](#page-130-11) and [Malitsky and](#page-138-3) [Tam](#page-138-3) [\(2023\)](#page-138-3). In spite of these achievements, fixed point methods seem less well suited to capturing in simple terms the most flexible splitting methods, such as the block-iterative asynchronous methods of [Bùi](#page-130-10) [\(2022](#page-130-10)*b*), [Bùi and Combettes](#page-131-6) [\(2022](#page-131-6)*b*), [Combettes and Eckstein](#page-132-5) [\(2018\)](#page-132-5) and [Johnstone and Eckstein](#page-137-3) [\(2022\)](#page-137-3), which were built using geometric arguments. The purpose of the present paper is to provide a standardized pattern for building and analysing splitting methods around the following geometric framework. It comprises an embedding step, where the initial Problem [1.1](#page-1-1) is replaced by a more tractable surrogate inclusion problem in an auxiliary space **X** from which the solutions to the original problem can be easily recovered. The second step is an iterative process in which the current iterate is projected onto a closed half-space that serves as an outer approximation to the surrogate solution set.

Framework 1.2. Geometric algorithmic template for solving Problem [1.1.](#page-1-1)

- (i) *Embedding.* Find a real Hilbert space **X**, a maximally monotone operator $\mathcal{M}: \mathsf{X} \to 2^{\mathsf{X}}$ and an operator $\mathcal{T}: \mathsf{X} \to \mathcal{H}$ such that $\mathcal{T}(\text{zer } \mathcal{M}) \subset \text{zer } M$. We call (X, M, T) an *embedding* of Problem [1.1.](#page-1-1)
- (ii) *Iterations.*

for $n = 0, 1, ...$ **H**_n is a closed half-space of **X** such that zer $\mathcal{M} \subset \mathbf{H}_n$ \mathbf{x}_{n+1} is a relaxed projection of \mathbf{x}_n onto \mathbf{H}_n . (1.5)

In optimization, the use of half-spaces as outer approximations to the solution set goes back to the cutting plane methods of [Cheney and Goldstein](#page-132-8) [\(1959](#page-132-8)*a*), [Kelley](#page-137-6) [\(1960\)](#page-137-6) and [Levitin and Polyak](#page-138-4) [\(1966\)](#page-138-4); see also [Laurent and Martinet](#page-137-7) [\(1970\)](#page-137-7), [Veinott](#page-143-6) [\(1967\)](#page-143-6) and [Zangwill](#page-144-7) [\(1969\)](#page-144-7). In monotone inclusion problems, modelling iterations as successive projections onto separating half-spaces occurs in several papers [\(Bauschke and Combettes](#page-127-5) [2001,](#page-127-5) [Combettes](#page-132-9) [2001](#page-132-9)*a*, [Solodov and Svaiter](#page-142-4) [1999](#page-142-4)*a*,*[b](#page-142-5)*). We aim at showing that Framework [1.2](#page-4-0) is sufficiently broad and flexible to encompass a wide array of existing methods while providing a template to create new ones. It will allow us to derive in a unified fashion simple proofs of existing convergence results. It will also make it possible to establish seamlessly strongly convergent variants of these algorithms. The proofs we provide are new, and so are some of the results.

The remainder of the paper is organized as follows. To make our presentation self-contained, Section [2](#page-5-0) covers the necessary mathematical background on monotone operator theory. It also contains various examples of maximally monotone operators and a detailed history of the field. In Section [3](#page-23-0) we present several models for decomposing M in Problem [1.1.](#page-1-1) These decompositions will generate the embeddings required in Framework [1.2](#page-4-0) and form the backbone of the splitting methods discussed in the paper. The geometric principles underlying our approach are presented in Section [4,](#page-30-0) where the main convergence theorems are laid out. In Section [5](#page-42-0) we study the proximal point algorithm and explore several of its facets. In Sections [6,](#page-57-0) [7](#page-66-0) and [8](#page-77-0) we study, respectively, the Douglas– Rachford, forward–backward–forward and forward–backward methods through the lens of Framework [1.2](#page-4-0) and capture a broad range of algorithms and applications by

embedding them in bigger spaces. Block-iterative Kuhn–Tucker and saddle projective splitting methods are addressed in Sections [9](#page-106-0) and [10,](#page-115-0) respectively. Finally, several extensions and variants of the results are discussed in Section [11.](#page-123-0)

2. Monotone operators

2.1. Notation and basic definitions

The material of this section can be found in [Bauschke and Combettes](#page-127-6) [\(2017\)](#page-127-6).

2.1.1. General notation

H and G are real Hilbert spaces, $\mathcal{B}(\mathcal{H}, \mathcal{G})$ is the space of bounded linear operators from H to G, $\mathcal{B}(\mathcal{H}) = \mathcal{B}(\mathcal{H}, \mathcal{H})$, and $\mathcal{H} \oplus \mathcal{G}$ denotes the Hilbert direct sum of H and G. The identity operator of H is denoted by Id_H, its scalar product by $\langle \cdot | \cdot \rangle_{\mathcal{H}}$, and the associated norm by $\|\cdot\|_{\mathcal{H}}$ (the subscripts will be omitted when the context is clear). The weak convergence of a sequence $(x_n)_{n \in \mathbb{N}}$ to x is denoted by $x_n \to x$, whereas $x_n \to x$ denotes its strong convergence; the set of weak sequential cluster points of $(x_n)_{n \in \mathbb{N}}$ is denoted by $\mathfrak{W}(x_n)_{n \in \mathbb{N}}$.

2.1.2. Sets

Let C be a subset of H . The interior of C is int C, the *indicator function* of C is

$$
\iota_C: \mathcal{H} \to]-\infty, +\infty] : x \mapsto \begin{cases} 0, & \text{if } x \in C, \\ +\infty, & \text{otherwise,} \end{cases} \tag{2.1}
$$

the *support function* of C is

$$
\sigma_C: \mathcal{H} \to [-\infty, +\infty] : x^* \mapsto \sup_{x \in C} \langle x | x^* \rangle,
$$
 (2.2)

and the *distance function* to C is

$$
d_C: \mathcal{H} \to]-\infty, +\infty] : x \mapsto \inf_{y \in C} ||x - y||. \tag{2.3}
$$

Suppose that C is convex. We let cone C denote the smallest cone that contains C and let sri C denote the *strong relative interior* of C, that is,

$$
\operatorname{sri} C = \{ x \in C \mid \text{cone}(-x + C) \text{ is a closed vector subspace of } \mathcal{H} \}. \tag{2.4}
$$

If H is finite-dimensional, sri C coincides with the *relative interior* ri C of C, i.e. the interior of C relative to the smallest affine subspace of H containing C. Suppose that C is nonempty, closed and convex. For every $x \in \mathcal{H}$,

$$
\text{proj}_C x \text{ is the unique point in } C \text{ such that } d_C(x) = \|x - \text{proj}_C x\|. \tag{2.5}
$$

This process defines the *projection operator* $proj_C : \mathcal{H} \to \mathcal{H}$ of C. The simple case of a closed half-space is central to our approach.

<https://doi.org/10.1017/S0962492923000065>Published online by Cambridge University Press

Example 2.1 [\(Bauschke and Combettes](#page-127-6) [2017,](#page-127-6) Example 29.20). Let $u^* \in \mathcal{H}$, let $\eta \in \mathbb{R}$, and suppose that $H = \{z \in \mathcal{H} \mid \langle z | u^* \rangle \leq \eta \} \neq \emptyset$. Let $x \in \mathcal{H}$ and set

$$
d = \begin{cases} \frac{\langle x | u^* \rangle - \eta}{\|u^*\|^2} u^*, & \text{if } \langle x | u^* \rangle > \eta, \\ 0, & \text{otherwise.} \end{cases}
$$
 (2.6)

Then $proj_H x = x - d$.

2.1.3. Functions

The set of minimizers of a function $f: \mathcal{H} \to]-\infty, +\infty]$ is denoted by Argmin f and, if it is a singleton, its unique element is denoted by argmin_{$x \in H f(x)$}. The *infimal convolution* of $f: \mathcal{H} \to]-\infty, +\infty]$ and $h: \mathcal{H} \to]-\infty, +\infty]$ is

$$
f \Box h: \mathcal{H} \to [-\infty, +\infty] : x \mapsto \inf_{y \in \mathcal{H}} (f(y) + h(x - y)). \tag{2.7}
$$

Let $\Gamma_0(\mathcal{H})$ denote the class of functions $f: \mathcal{H} \to [-\infty, +\infty]$ which are lower semicontinuous, convex, and such that dom $f = \{x \in \mathcal{H} \mid f(x) < +\infty\} \neq \emptyset$. Let $f \in \Gamma_0(\mathcal{H})$. The *conjugate* of f is

$$
\Gamma_0(\mathcal{H}) \ni f^* \colon x^* \mapsto \sup_{x \in \mathcal{H}} (\langle x \mid x^* \rangle - f(x)). \tag{2.8}
$$

For every $x \in \mathcal{H}$,

prox $_f$ x is the unique minimizer over H of $y \mapsto f(y) + \frac{1}{2}$ 2 $||x - y||^2$. (2.9)

This process defines the *proximity operator* $prox_f : \mathcal{H} \to \mathcal{H}$ of f. We have

$$
(\forall \gamma \in]0, +\infty[)(\forall x \in \mathcal{H}) \quad x = \text{prox}_{\gamma f} \ x + \gamma \ \text{prox}_{f^*/\gamma}(x/\gamma). \tag{2.10}
$$

The *Moreau envelope* of f of parameter $\gamma \in [0, +\infty)$ is

$$
\gamma_f = f \Box \left(\frac{1}{2\gamma} ||\cdot||^2\right). \tag{2.11}
$$

2.1.4. Set-valued operators

Let $M: \mathcal{H} \to 2^{\mathcal{H}}$. The *graph* of M is

$$
\text{gra}\,M = \{(x, x^*) \in \mathcal{H} \times \mathcal{H} \mid x^* \in Mx\}.\tag{2.12}
$$

The *inverse* of M is the operator M^{-1} : $\mathcal{H} \rightarrow 2^{\mathcal{H}}$ defined through the relation

$$
(\forall (x, x^*) \in \mathcal{H} \times \mathcal{H}) \quad x^* \in Mx \quad \Leftrightarrow \quad x \in M^{-1}x^*.
$$
 (2.13)

Thus,

$$
\text{gra}\,M^{-1} = \{(x^*, x) \in \mathcal{H} \times \mathcal{H} \mid (x, x^*) \in \text{gra}\,M\}.
$$
 (2.14)

The set of *fixed points* of *M* is

$$
\text{Fix } M = \{ x \in \mathcal{H} \mid x \in Mx \},\tag{2.15}
$$

the set of *zeros* of M is

$$
\text{zer } M = M^{-1}0 = \{ x \in \mathcal{H} \mid 0 \in Mx \},\tag{2.16}
$$

and the *resolvent* of *M* is the operator

$$
J_M = (\text{Id} + M)^{-1}.
$$
 (2.17)

In other words,

$$
(\forall x \in \mathcal{H})(\forall p \in \mathcal{H}) \quad p \in J_M x \iff (p, x - p) \in \text{gra } M,\tag{2.18}
$$

and therefore

$$
zer M = Fix J_M.
$$
 (2.19)

We have

$$
(\forall \gamma \in]0, +\infty[)(\forall x \in \mathcal{H}) \quad x - J_{\gamma M} x = \gamma J_{M^{-1}/\gamma}(x/\gamma). \tag{2.20}
$$

The *Yosida approximation* of index $\gamma \in [0, +\infty[$ of *M* is

$$
\gamma M = \frac{\text{Id} - J_{\gamma M}}{\gamma} = (\gamma \text{Id} + M^{-1})^{-1} = (J_{\gamma^{-1} M^{-1}}) \circ \gamma^{-1} \text{Id}
$$
 (2.21)

and it satisfies

$$
zer M = zer^{\gamma} M. \tag{2.22}
$$

The *domain* of *M* is

$$
\text{dom}\,M = \{x \in \mathcal{H} \mid Mx \neq \emptyset\} \tag{2.23}
$$

and the *range* of M is

$$
\operatorname{ran} M = \bigcup_{x \in \operatorname{dom} M} Mx = \{ x^* \in \mathcal{H} \mid (\exists x \in \operatorname{dom} M) \ x^* \in Mx \}. \tag{2.24}
$$

We have

$$
dom M^{-1} = ran M
$$
 and $ran M^{-1} = dom M$. (2.25)

If, for some $x \in \mathcal{H}$, Mx is a singleton, we let Mx denote its single element. We say that M is *injective* if $(\forall x \in \mathcal{H})(\forall y \in \mathcal{H})$ $Mx \cap My \neq \emptyset \Rightarrow x = y$. Finally, given $A: \mathcal{H} \to 2^{\mathcal{H}}, B: \mathcal{G} \to 2^{\mathcal{G}}, L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$ and $\alpha \in \mathbb{R}$, we set

$$
A + \alpha L^* \circ B \circ L: \quad \mathcal{H} \to 2^{\mathcal{H}}x \mapsto \{x^* + \alpha L^* y^* \mid x^* \in Ax \text{ and } y^* \in B(Lx)\}.
$$
 (2.26)

2.1.5. Monotone operators

Let $M: \mathcal{H} \to 2^{\mathcal{H}}$. Then M is *monotone* if

$$
(\forall (x, x^*) \in \text{gra } M)(\forall (y, y^*) \in \text{gra } M) \quad \langle x - y | x^* - y^* \rangle \ge 0 \tag{2.27}
$$

Figure 2.1. (a) Graph of a monotone, but not maximally monotone, operator: the point (x_0, x_0^*) can be added to the graph and the resulting graph remains monotone. (b) Graph of a maximally monotone operator: adding any point to the graph does not preserve its monotonicity.

and *maximally monotone* if, further, there exists no monotone operator $A: \mathcal{H} \to 2^{\mathcal{H}}$ such that gra $M \subset \text{gra } A \neq \text{gra } M$, that is (see Figure [2.1\)](#page-8-0),

$$
(\forall (x, x^*) \in \mathcal{H} \times \mathcal{H})
$$

\n
$$
[(x, x^*) \in \text{gra } M \iff (\forall (y, y^*) \in \text{gra } M) \langle x - y | x^* - y^* \rangle \ge 0].
$$
 (2.28)

We have

$$
M
$$
 maximally monotone \Rightarrow zer M is closed and convex. (2.29)

Let $\beta \in [0, +\infty]$. Then *M* is β -*strongly monotone* if *M* − β Id is monotone, that is,

$$
(\forall (x, x^*) \in \text{gra } M)(\forall (y, y^*) \in \text{gra } M) \quad \langle x - y \mid x^* - y^* \rangle \ge \beta \|x - y\|^2. \tag{2.30}
$$

Now let D be a nonempty subset of H, let $\alpha \in [0, +\infty)$, and let $M : D \to H$. Then 𝑀 is *nonexpansive* if

$$
(\forall x \in D)(\forall y \in D) \quad ||Mx - My|| \le ||x - y||, \tag{2.31}
$$

 α -*averaged* if $\alpha \le 1$ and Id + $\alpha^{-1}(M - \text{Id})$ is nonexpansive, α -*cocoercive* if M^{-1} is α -strongly monotone, that is,

$$
(\forall x \in D)(\forall y \in D) \quad \langle x - y \mid Mx - My \rangle \ge \alpha ||Mx - My||^2, \tag{2.32}
$$

and *firmly nonexpansive* if it is 1-cocoercive. Alternatively,

M is firmly nonexpansive ⇔ $2M - Id$ is nonexpansive. (2.33)

The following result is known as the Baillon–Haddad theorem.

Lemma 2.2 [\(Baillon and Haddad](#page-127-7) [1977\)](#page-127-7). Let $\alpha \in [0, +\infty[$ and let $f: \mathcal{H} \to \mathbb{R}$ be convex, Fréchet-differentiable, and such that ∇f is $1/\alpha$ -Lipschitzian. Then ∇f is α -cocoercive.

2.2. History

Monotonicity goes back to classical calculus and the notion of an increasing realvalued function defined on an interval $D \subset \mathbb{R}$, i.e. a function $f: D \to \mathbb{R}$ that satisfies

$$
(\forall x \in D)(\forall y \in D) \quad (x - y)(f(x) - f(y)) \ge 0. \tag{2.34}
$$

The special properties enjoyed by such functions have long been recognized; see for instance [Darboux](#page-133-10) [\(1875\)](#page-133-10), [Froda](#page-135-5) [\(1929\)](#page-135-5) and [Hahn](#page-136-6) [\(1921\)](#page-136-6). The monotonicity condition [\(2.34\)](#page-9-0) is also tied to the infancy of the theory of convex functions. Thus [Jensen](#page-137-8) [\(1906\)](#page-137-8) showed that, if D is open and $g: D \to \mathbb{R}$ is a twice differentiable function with derivative f , then [\(2.34\)](#page-9-0) implies that g is convex. On the numerical side, [\(2.34\)](#page-9-0) is an important property in connection with solving iteratively the root finding problem [\(Papakonstantinou and Tapia](#page-140-5) [2013\)](#page-140-5)

find
$$
x \in D
$$
 such that $f(x) = 0$. (2.35)

Monotone operators on $\mathbb R$ also appeared in nonlinear circuit theory in the 1940s in the form of quasi-linear resistors [\(Duffin](#page-134-5) [1946,](#page-134-5) [1947,](#page-134-6) [1948\)](#page-134-7). A quasi-linear resistor is a two-pole circuit element characterized by the property that the current going through it increases smoothly with the voltage across it. In other words, the transformation underlying its current–voltage characteristic is differentiable and increasing. Dipoles with monotonic characteristics were further investigated in Millar (1951). To study networks involving a broader range of devices, [Minty](#page-139-5) [\(1960,](#page-139-5) [1961\)](#page-139-6) extended this concept to maximally monotone set-valued transformations on R; see Figure [2.2](#page-10-0) and [Cederbaum](#page-131-7) [\(1962\)](#page-131-7) for examples. Interestingly, as will be discussed shortly, Minty turned out to be one of the founders of monotone operator theory. For further relevant early work on the connections between monotone operators and network theory, see [Berge and Ghouila-Houri](#page-128-4) [\(1962\)](#page-128-4) and [Desoer](#page-134-8) [and Wu](#page-134-8) [\(1974\)](#page-134-8) and, for more abstract ramifications, see [Doležal](#page-134-3) [\(1979](#page-134-3)*b*) and [Rockafellar](#page-141-0) [\(1984\)](#page-141-0).

Another precursor of monotonicity is found in linear functional analysis, where a linear operator $M: H \supset D \to H$ is declared accretive if [\(Kato](#page-137-9) [1980\)](#page-137-9)

$$
(\forall x \in D) \quad \langle x \mid Mx \rangle \ge 0. \tag{2.36}
$$

In this context, the notion of a maximally accretive operator was introduced in [Phillips](#page-140-6) [\(1959\)](#page-140-6). Accretive operators are also central to passive linear network theory [\(Beltrami](#page-128-5) [1972,](#page-128-5) [Zames and Falb](#page-144-8) [1968\)](#page-144-8). One of the first instances of [\(2.36\)](#page-9-1) in electrical networks is the current–voltage transformation of the four-pole circuit element known as an ideal gyrator [\(Tellegen](#page-143-7) [1948\)](#page-143-7).

Figure 2.2. Current–voltage characteristics of quasi-linear resistors as monotone operators from $\mathbb R$ to $2^{\mathbb R}$. (a) Breakdown diodes in series [\(Reich](#page-141-7) [1961\)](#page-141-7). (b) Breakdown diode and resistance in series [\(Reich](#page-141-7) [1961\)](#page-141-7). (c) Anode–dynode beam-deflection tube [\(Reich](#page-141-7) [1961\)](#page-141-7). (d) The maximally monotone current–voltage characteristic of [Minty](#page-139-6) [\(1961\)](#page-139-6).

The above notions of increasing functions and positive operators can be brought together by considering an operator $M: H \supset D \to H$ such that

$$
(\forall x \in D)(\forall x \in D) \quad \langle x - y \mid Mx - My \rangle \ge 0. \tag{2.37}
$$

Instances of [\(2.37\)](#page-11-0) appear implicitly in [Golomb](#page-136-7) [\(1935\)](#page-136-7) and, more explicitly, in Vaĭnberg [\(1956,](#page-143-8) [1959\)](#page-143-9) in connection with the existence of solutions to Hammerstein integral equations; see also [Golomb](#page-136-8) [\(1936\)](#page-136-8) for more general types of equations. Another instance, which corresponds to what is now called strict monotonicity, appears in [Buck](#page-130-13) [\(1956\)](#page-130-13), where H is the standard Euclidean space. The systematic study of operators satisfying [\(2.37\)](#page-11-0) started in 1960 and opened an important new chapter of nonlinear functional analysis. Three independent papers submitted that year are associated with the birth of monotone operator theory.

- Kačurovskiı̆ [\(1960\)](#page-137-0), in an article submitted in February 1960, used the term *monotone* to describe an operator that satisfies [\(2.37\)](#page-11-0). This paper concerned the monotonicity of the gradient of a differentiable convex function (see also Vaĭnberg and Kačurovskiĭ [1959\)](#page-143-10) and the existence of solutions to certain nonlinear equations. It also introduced strongly monotone operators.
- [Zarantonello](#page-144-0) [\(1960\)](#page-144-0), in a technical report completed in June 1960, called [\(2.37\)](#page-11-0) an (isotonically) monotonicity property and discussed supra-unitary (in modern language, strongly monotone) operators. In connection with the solution of nonlinear equations, an important result of [Zarantonello](#page-144-0) [\(1960\)](#page-144-0) is that, if $M: \mathcal{H} \to \mathcal{H}$ is monotone and Lipschitzian, then Id + M is surjective.
- [Minty](#page-139-7) [\(1962\)](#page-139-7), in an article submitted in December 1960, also called $M: D \rightarrow$ H monotone if it satisfies [\(2.37\)](#page-11-0). In addition, he introduced the fundamental concept of maximal monotonicity and established key connections with nonexpansive operators. Although, strictly speaking, his definitions dealt with single-valued operators, he established results on monotone relations that naturally suggest extensions to the set-valued case [\(1.1\)](#page-1-2). According to [Browder](#page-130-14) [\(1965\)](#page-130-14), who initiated the study of set-valued monotone operators in Banach spaces, the Hilbertian setting was worked out by Minty in unpublished notes.

Accounts of the history of the development of monotone operator theory in the 1960s can be found in [Borwein](#page-129-7) [\(2010\)](#page-129-7), [Browder](#page-130-0) [\(1968/1976\)](#page-130-0), [Kačurovski˘ı](#page-137-10) [\(1968\)](#page-137-10), [Lions](#page-138-5) [\(1969,](#page-138-5) Section 2.12), [Minty](#page-139-8) [\(1969\)](#page-139-8) and [Va˘ınberg](#page-143-11) [\(1972,](#page-143-11) Chapter VI). In that period, the main mathematical areas of applications were nonlinear equations, partial differential equations, boundary-value problems, nonexpansive semigroups, convex analysis, evolution equations and variational inequalities; see [Brézis\(1966\)](#page-129-8), [Browder](#page-130-15) [\(1963,](#page-130-15) [1968/1976\)](#page-130-0), [Ghizzetti](#page-136-0) [\(1969\)](#page-136-0), Kōmura [\(1967\)](#page-137-11), [Leray and Lions](#page-138-6) [\(1965\)](#page-138-6), [Moreau](#page-139-9) [\(1966–1967\)](#page-139-9), [Vishik](#page-144-9) [\(1961\)](#page-144-9) and [Zarantonello](#page-145-0) [\(1971\)](#page-145-0), and their bibliographies. At the same time, monotonicity continued to be used in the analysis of networks and systems, for instance in [Zames](#page-144-10) [\(1966](#page-144-10)*a*,*[b](#page-144-11)*), where it is known as incremental positiveness; see also [Desoer and Vidyasagar](#page-134-2) [\(1975\)](#page-134-2), where monotonicity is called incremental passivity. The main use of monotone operators was to establish existence, uniqueness orstability results in a variety of nonlinear problems in analysis.

2.3. Examples of maximally monotone operators

The following example concerns single-valued operators; Examples [2.4–](#page-12-0)[2.10](#page-12-1) follow from it [\(Bauschke and Combettes](#page-127-6) [2017,](#page-127-6) Chapter 20).

Example 2.3 [\(Minty](#page-139-10) [1963\)](#page-139-10). Let $A: \mathcal{H} \rightarrow \mathcal{H}$ be monotone and *hemicontinuous* (in particular, continuous) in the sense that

$$
(\forall (x, y, z) \in \mathcal{H}^3) \quad \lim_{0 < \alpha \downarrow 0} \langle z | A(x + \alpha y) \rangle = \langle z | Ax \rangle. \tag{2.38}
$$

Then A is maximally monotone.

Example 2.4. Let $T: \mathcal{H} \to \mathcal{H}$ be nonexpansive and let $\alpha \in [-1, 1]$. Then Id + αT is maximally monotone. In particular, set $A = Id - T$. Then A is maximally monotone and zer $A = Fix T$.

Example 2.5. Let $A: H \to H$ be cocoercive. Then A is maximally monotone.

Example 2.6. Let $M: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone and set $A = J_M$. Then A is maximally monotone and zer $A = \text{zer } M^{-1}$.

Example 2.7. Let $M: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, let $\gamma \in]0, +\infty[$, and set $A = \gamma M$ (see [\(2.21\)](#page-7-0)). Then A is γ -cocoercive, hence maximally monotone, and zer $A = \text{zer } M$.

Example 2.8. Let $f \in \Gamma_0(\mathcal{H})$ and set $A = \text{prox}_f$. Then A is maximally monotone.

Example 2.9. Let C be a nonempty closed convex subset of H and set $A = \text{proj}_C$. Then A is maximally monotone.

Example 2.10. Let $A \in \mathcal{B}(\mathcal{H})$ be a *skew* operator, i.e. $A^* = -A$. Then A is maximally monotone.

Here is an elementary example of a maximally monotone set-valued operator on the real line.

Example 2.11. Let $a \in \mathbb{R}$ and $b \in \mathbb{R}$ be such that $a < b$, let $f : [a, b] \to \mathbb{R}$ be increasing (see [\(2.34\)](#page-9-0)), and define

$$
(\forall x \in \mathbb{R}) \quad Ax = \begin{cases} \emptyset, & \text{if } x \notin [a, b], \\]-\infty, f(a)], & \text{if } x = a, \\ [f(b), +\infty[, & \text{if } x = b, \\ [\sup f([a, x]), \inf f([x, b])], & \text{if } x \in]a, b[]. \end{cases}
$$
(2.39)

Then A is maximally monotone.

The following example is a central result in variational methods; for a special case see [Minty](#page-139-11) [\(1964,](#page-139-11) corollary on page 244).

Example 2.12 [\(Moreau](#page-139-12) [1965\)](#page-139-12). Let $f: H \rightarrow]-\infty, +\infty]$ be proper. Then the *subdifferential*

$$
\partial f: \mathcal{H} \to 2^{\mathcal{H}}: x \mapsto \{x^* \in \mathcal{H} \mid (\forall y \in \mathcal{H}) \langle y - x \mid x^* \rangle + f(x) \le f(y)\} \tag{2.40}
$$

of f is monotone and (*Fermat's rule*) zer $\partial f = \text{Argmin } f$. If $f \in \Gamma_0(\mathcal{H})$, then ∂f is maximally monotone and $(\partial f)^{-1} = \partial f^*$.

Example 2.13 [\(Rockafellar](#page-141-8) [1970](#page-141-8)*a***, Theorem 24.3).** Let $A: \mathbb{R} \to 2^{\mathbb{R}}$ be maximally monotone. Then there exists $f \in \Gamma_0(\mathbb{R})$ such that $A = \partial f$.

Example 2.14. Let C be a nonempty convex subset of H. Then, setting $f = \iota_C$ in Example [2.12,](#page-13-0) we conclude that the *normal cone* operator

$$
N_C = \partial \iota_C: \mathcal{H} \to 2^{\mathcal{H}}
$$

\n
$$
x \mapsto \begin{cases} \{x^* \in \mathcal{H} \mid (\forall y \in C) \ \langle y - x \mid x^* \rangle \le 0 \}, & \text{if } x \in C, \\ \varnothing, & \text{otherwise} \end{cases}
$$
\n(2.41)

of C is monotone and that it is maximally monotone if C is closed, in which case $(N_C)^{-1} = \partial \sigma_C.$

Example 2.15. Let V be a closed vector subspace of H . Then it follows from Example [2.14](#page-13-1) that

$$
N_V: \mathcal{H} \to 2^{\mathcal{H}}: x \mapsto \begin{cases} V^{\perp}, & \text{if } x \in V, \\ \varnothing, & \text{otherwise} \end{cases}
$$
 (2.42)

is maximally monotone and $(N_V)^{-1} = N_{V^{\perp}}$.

The next two examples involve the Laplacian operator and are central to partial differential equations [\(Attouch, Buttazzo and Michaille](#page-127-8) [2014,](#page-127-8) [Barbu](#page-127-4) [2010,](#page-127-4) [Brézis](#page-129-9) [1971,](#page-129-9) [Ghoussoub](#page-136-2) [2009,](#page-136-2) [Zeidler](#page-145-1) [1990\)](#page-145-1).

Example 2.16 [\(Attouch](#page-127-8) *et al.* **[2014,](#page-127-8) Theorem 17.2.10).** Let Ω be a nonempty bounded open subset of \mathbb{R}^N , suppose that $\mathcal{H} = L^2(\Omega)$, and set

$$
A: \mathcal{H} \to 2^{\mathcal{H}}: x \mapsto \begin{cases} -\Delta x, & \text{if } x \in H_0^1(\Omega) \text{ and } \Delta x \in \mathcal{H}, \\ \varnothing, & \text{otherwise.} \end{cases} \tag{2.43}
$$

Then it follows from Example [2.12](#page-13-0) that A is maximally monotone as the subdifferential of the function

$$
f: \mathcal{H} \to]-\infty, +\infty] : x \mapsto \begin{cases} \frac{1}{2} \int_{\Omega} ||\nabla x(\omega)||^2 d\omega, & \text{if } x \in H_0^1(\Omega), \\ +\infty, & \text{otherwise,} \end{cases}
$$
(2.44)

which is in $\Gamma_0(\mathcal{H})$. In addition, if bdry Ω is of class \mathcal{C}^2 , then dom $\partial f = H^2(\Omega) \cap$ $H_0^1(\Omega)$.

Example 2.17 [\(Attouch](#page-127-8) *et al.* **[2014,](#page-127-8) Section 17.2.9).** Let Ω be a nonempty bounded open subset of \mathbb{R}^N such that bdry Ω is of class \mathcal{C}^2 , let $\partial/\partial v$ denote the outward normal derivative to bdry Ω, suppose that $\mathcal{H} = L^2(\Omega)$, let $h \in \mathcal{H}$, and set

A:
$$
\mathcal{H} \to 2^{\mathcal{H}}
$$

\n $x \mapsto \begin{cases}\n-\Delta x - h, & \text{if } x \in H^2(\Omega) \text{ and } \partial x/\partial \nu = 0 \text{ a.e. on bdry }\Omega, \\
\emptyset, & \text{otherwise.} \n\end{cases}$ (2.45)

Then it follows from Example [2.12](#page-13-0) that A is maximally monotone as the subdifferential of the function

$$
f: \mathcal{H} \to]-\infty, +\infty]
$$

\n
$$
x \mapsto \begin{cases} \frac{1}{2} \int_{\Omega} ||\nabla x(\omega)||^2 d\omega - \int_{\Omega} x(\omega)h(\omega) d\omega, & \text{if } x \in H^1(\Omega), \\ +\infty, & \text{otherwise,} \end{cases}
$$
 (2.46)

 \overline{a} which is in $\Gamma_0(\mathcal{H})$.

The next scenario arises in the study of evolution equations by monotonicity methods [\(Brézis](#page-129-9) [1971,](#page-129-9) [1973,](#page-129-0) [Showalter](#page-142-0) [1997,](#page-142-0) [Zeidler](#page-145-1) [1990\)](#page-145-1).

Example 2.18 [\(Brézis](#page-129-9) [1971,](#page-129-9) Example 4; [Showalter](#page-142-0) [1997,](#page-142-0) Chapter IV; [Zeidler](#page-145-1) [1990,](#page-145-1) Chapter 32). Let H be a separable real Hilbert space, let $T \in [0, +\infty)$, and suppose that $\mathcal{H} = L^2([0, T]; H)$. For every $y \in \mathcal{H}$, the function $x: [0, T] \to$ H: $t \mapsto \int_0^t y(s) ds$ is differentiable a.e. on]0, T[with $x' = y$ a.e. Define

$$
H^{1}([0, T]; \mathsf{H}) = \{x \in \mathcal{H} \mid x' \in L^{2}([0, T]; \mathsf{H})\},\tag{2.47}
$$

let $x_0 \in H$, and set

$$
A: \mathcal{H} \to 2^{\mathcal{H}}: x \mapsto \begin{cases} \{x'\}, & \text{if } x \in H^1([0, T]; \mathsf{H}) \text{ and } x(0) = x_0, \\ \varnothing, & \text{otherwise} \end{cases}
$$
 (2.48)

and

$$
B: \mathcal{H} \to 2^{\mathcal{H}}: x \mapsto \begin{cases} \{x'\}, & \text{if } x \in H^1([0, T]; \mathsf{H}) \text{ and } x(0) = x(T), \\ \varnothing, & \text{otherwise.} \end{cases} \tag{2.49}
$$

Then A and B are maximally monotone.

Example 2.19 [\(Brézis](#page-129-0) [1973,](#page-129-0) Exemple 2.3.3). Let $(\Omega, \mathcal{F}, \mu)$ be a measure space, let H be a separable real Hilbert space, let $A: H \rightarrow 2^H$ be maximally monotone, and set $\mathcal{H} = L^2((\Omega, \mathcal{F}, \mu); \mathsf{H})$. Define $A: \mathcal{H} \to 2^{\mathcal{H}}$ via

$$
(\forall x \in \mathcal{H})(\forall x^* \in \mathcal{H})
$$
 $(x, x^*) \in \text{gra } A \Leftrightarrow$
for μ -almost every $\omega \in \Omega$, $(x(\omega), x^*(\omega)) \in \text{gra } A$, (2.50)

and suppose that one of the following holds:

- (i) $\mu(\Omega) < +\infty$.
- (ii) $0 \in A0$.

Then A is maximally monotone.

We now turn to an equilibrium problem in the sense of [Blum and Oettli](#page-129-10) [\(1994\)](#page-129-10).

Example 2.20 [\(Aoyama, Kimura and Takahashi](#page-126-8) [2008\)](#page-126-8). Let C be a nonempty closed convex subset of H and suppose that $F: C \times C \rightarrow \mathbb{R}$ satisfies the following:

- (i) $(\forall x \in C) F(x, x) = 0.$
- (ii) $(\forall x \in C)(\forall y \in C) F(x, y) + F(y, x) \leq 0.$
- (iii) For every $x \in C$, $F(x, \cdot): C \to \mathbb{R}$ is lower semicontinuous and convex.
- (iv) $(\forall x \in C)(\forall y \in C)(\forall z \in C)$ lim_{0< $\varepsilon \to 0$} $F((1 \varepsilon)x + \varepsilon z, y) \leq F(x, y)$.

Set

$$
A: \mathcal{H} \to 2^{\mathcal{H}}
$$

\n
$$
x \mapsto \begin{cases} \{x^* \in \mathcal{H} \mid (\forall y \in C) \ F(x, y) + \langle x - y | x^* \rangle \ge 0 \}, & \text{if } x \in C, \\ \varnothing, & \text{otherwise.} \end{cases}
$$
 (2.51)

Then A is maximally monotone and zer $A = \{x \in C \mid (\forall y \in C) F(x, y) \ge 0\}$ is the set of *equilibria* of *F*.

We conclude with an example in the theory of saddle functions.

Example 2.21 [\(Rockafellar](#page-141-2) [1970](#page-141-2)*b***).** Let $F: \mathcal{H} \oplus \mathcal{G} \rightarrow [-\infty, +\infty]$ be a *saddle function*, i.e. a convex–concave function which is proper and closed in the sense of [Rockafellar](#page-141-2) [\(1970](#page-141-2)*b*, [1971\)](#page-141-9) (e.g. for every $x \in \mathcal{H}$ and every $y \in \mathcal{G}, -F(x, \cdot) \in \Gamma_0(\mathcal{G})$ and $F(\cdot, y) \in \Gamma_0(\mathcal{H})$). Set

$$
(\forall x \in \mathcal{H})(\forall y \in \mathcal{G}) \quad A(x, y) = \partial F(\cdot, y)(x) \times \partial (-F(x, \cdot))(y). \tag{2.52}
$$

Then A is maximally monotone and

$$
\text{zer}\,A = \{(x, y) \in \mathcal{H} \oplus \mathcal{G} \mid F(x, y) = \inf F(\mathcal{H}, y) = \sup F(x, \mathcal{G})\} \tag{2.53}
$$

is the set of *saddle points* of F.

The following illustration is set in the powerful perturbation framework of [Rockafellar](#page-141-10) [\(1969,](#page-141-10) [1970](#page-141-2)*b*, [1974\)](#page-141-11) (see also [Joly and Laurent](#page-137-12) [1971\)](#page-137-12), which provides a systematic tool to construct duality frameworks in minimization problems.

Example 2.22. Let V be a real Hilbert space, let $f: \mathcal{H} \to]-\infty, +\infty]$ be a proper function, and consider the primal problem

$$
\underset{x \in \mathcal{H}}{\text{minimize}} \quad f(x). \tag{2.54}
$$

Let $F: \mathcal{H} \oplus \mathcal{V} \to [-\infty, +\infty]$ be a *perturbation* of f, i.e. ($\forall x \in \mathcal{H}$) $f(x) = F(x, 0)$. The associated *Lagrangian* is

$$
\mathcal{L}_F: \mathcal{H} \oplus \mathcal{V} \mapsto [-\infty, +\infty] : (x, v^*) \mapsto \inf_{v \in \mathcal{V}} (F(x, v) - \langle v \mid v^* \rangle), \tag{2.55}
$$

the associated *dual problem* is

$$
\underset{\nu^* \in \mathcal{V}}{\text{minimize}} \quad \underset{x \in \mathcal{H}}{\text{sup}} (-\mathcal{L}_F(x, \nu^*)),\tag{2.56}
$$

and the associated *saddle operator* is

$$
\mathcal{S}_F: \mathcal{H} \oplus \mathcal{V} \to 2^{\mathcal{H} \oplus \mathcal{V}}: (x, v^*) \mapsto \partial(\mathcal{L}_F(\cdot, v^*))(x) \times \partial(-\mathcal{L}_F(x, \cdot))(v^*). \tag{2.57}
$$

It follows from Example [2.21](#page-15-0) that S_F is maximally monotone. In addition, if $(x, v^*) \in \text{zer } S_F$, then x solves [\(2.54\)](#page-15-1) and v^* solves [\(2.56\)](#page-16-0).

2.4. Basic theory

2.4.1. Operations preserving maximal monotonicity

The examples of Section [2.3](#page-12-2) can be combined in various fashions to create maximally monotone operators.

Lemma 2.23 [\(Bauschke and Combettes](#page-127-6) [2017,](#page-127-6) Proposition 20.22). Let $A: H \rightarrow$ $2^{\mathcal{H}}$ be maximally monotone, let $z \in \mathcal{H}$, let $u \in \mathcal{H}$, and let $\gamma \in]0, +\infty[$. Then A^{-1} and $x \mapsto u + \gamma A(x + z)$ are maximally monotone.

Lemma 2.24 [\(Bauschke and Combettes](#page-127-6) [2017,](#page-127-6) Proposition 23.18). Let $(H_i)_{i \in I}$ be a finite family of real Hilbert spaces, set

$$
\mathcal{H} = \bigoplus_{i \in I} \mathcal{H}_i,\tag{2.58}
$$

and, for every $i \in I$, let $A_i: \mathcal{H}_i \to 2^{\mathcal{H}_i}$ be maximally monotone. Set

$$
A: \mathcal{H} \to 2^{\mathcal{H}}: (x_i)_{i \in I} \mapsto \underset{i \in I}{\times} A_i x_i. \tag{2.59}
$$

Then A is maximally monotone.

Lemma 2.25. Let $\beta \in]0, +\infty[$, let $A: \mathcal{H} \to 2^{\mathcal{H}}$, let $U \in \mathcal{B}(\mathcal{H})$ be self-adjoint and β -strongly monotone, and let $\mathcal X$ be the real Hilbert space obtained by endowing H with the scalar product $(x, y) \mapsto \langle Ux | y \rangle$. Then the following hold:

- (i) $\text{zer}(U^{-1} \circ A) = \text{zer } A$.
- (ii) Suppose that $A: \mathcal{H} \to 2^{\mathcal{H}}$ is maximally monotone. Then $U^{-1} \circ A: \mathcal{X} \to 2^{\mathcal{X}}$ is maximally monotone.
- (iii) Let $\alpha \in]0, +\infty[$ and suppose that $A: \mathcal{H} \to \mathcal{H}$ is α -cocoercive. Then $U^{-1} \circ A : \mathcal{X} \to 2^{\mathcal{X}}$ is $\alpha \beta$ -cocoercive.

Proof. We note that [\(i\)](#page-16-1) is clear and [\(ii\)](#page-16-2) is proved in Combettes and V \tilde{u} [\(2014,](#page-133-11) Lemma 3.7(i)).

[\(iii\)](#page-16-3) Take $(x, y) \in \mathcal{H} \times \mathcal{H}$. Then

$$
\langle x - y | (U^{-1} \circ A)x - (U^{-1} \circ A)y \rangle_{\mathcal{X}} = \langle x - y | Ax - Ay \rangle_{\mathcal{H}}
$$

\n
$$
\geq \alpha ||Ax - Ay||_{\mathcal{H}}^2.
$$
 (2.60)

However, $||U^{-1}x||_{\mathcal{X}}^2 = \langle x | U^{-1}x \rangle_{\mathcal{H}} \le ||U||^{-1} ||x||_{\mathcal{H}}^2$ and $||U||^{-1} \le \beta^{-1}$ [\(Kato](#page-137-9) [1980,](#page-137-9) Section VI.2.6).

Lemma 2.26 [\(Bauschke and Combettes](#page-127-6) [2017,](#page-127-6) Theorem 25.3; [Boţ](#page-129-11) [2010,](#page-129-11) Section 24; [Pennanen](#page-140-7) [2000,](#page-140-7) Corollary 4.2(a)). Let $A: H \to 2^H$ and $B: \mathcal{G} \to 2^G$ be maximally monotone, let $L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$, and suppose that

$$
cone(L(\text{dom } A) - \text{dom } B) \text{ is a closed vector subspace of } G. \tag{2.61}
$$

Then $A + L^* \circ B \circ L$ is maximally monotone.

Lemma 2.27 [\(Bauschke and Combettes](#page-127-6) [2017,](#page-127-6) Corollary 25.5). Let A : $\mathcal{H} \rightarrow 2^{\mathcal{H}}$ and $B: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone and such that one of the following holds:

- (i) cone (dom $A - \text{dom } B$) is a closed vector subspace of H.
- (ii) dom $B = H$.
- (iii) dom $A \cap \text{int dom } B \neq \emptyset$.

Then $A + B$ is maximally monotone.

Lemma 2.28 [\(Alimohammady, Ramazannejad and Roohi](#page-126-9) [2014\)](#page-126-9). Let $A: H \rightarrow$ $2^{\mathcal{H}}$ be maximally monotone and let $B: \mathcal{H} \rightarrow 2^{\mathcal{H}}$ be monotone and such that dom $B = H$ and $A - B$ is monotone. Then $A - B$ is maximally monotone.

Lemma 2.29. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone. Define the *parallel sum* of A and B as

$$
A \sqcup B = (A^{-1} + B^{-1})^{-1} \tag{2.62}
$$

and suppose that cone (ran A – ran B) is a closed vector subspace of H . Then $A \square B$ is maximally monotone.

Proof. This follows from [\(2.25\)](#page-7-1), Lemma [2.23](#page-16-4) and Lemma [2.27\(](#page-17-0)[i\)](#page-17-1). \Box

Lemma 2.30 [\(Becker and Combettes](#page-128-6) [2014\)](#page-128-6). Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{G} \to 2^{\mathcal{G}}$ be maximally monotone, and let $L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$. Define the *parallel composition* of A with L as

$$
L \triangleright A = (L \circ A^{-1} \circ L^*)^{-1}.
$$
 (2.63)

Suppose that

$$
cone(\operatorname{ran} A - L^*(\operatorname{ran} B)) \text{ is a closed vector subspace of } \mathcal{H}. \tag{2.64}
$$

Then $(L \triangleright A) \square B$ is a maximally monotone operator from $\mathcal G$ to $2^{\mathcal G}$.

Example 2.31 [\(Combettes](#page-132-10) [2023\)](#page-132-10). Let $L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$ be such that $||L|| \leq 1$ and let $B: \mathcal{G} \to 2^{\mathcal{G}}$ be maximally monotone. Define the *resolvent composition* of B with L as

$$
L \circ B = L^* \triangleright (B + \text{Id}_{\mathcal{G}}) - \text{Id}_{\mathcal{H}}
$$
\n(2.65)

and the *resolvent cocomposition* of *B* with *L* as $L \cdot B = (L \cdot B^{-1})^{-1}$. Then $L \cdot B$ and $L \bullet B$ are maximally monotone operators from H to $2^{\mathcal{H}}$.

Example 2.32. Let $0 < p \in \mathbb{N}$, let $(\omega_k)_{1 \leq k \leq p}$ be a family in [0, 1] such that $\sum_{k=1}^{p} \omega_k = 1$, and let $(A_k)_{1 \le k \le p}$ be maximally monotone operators from H to $2^{\mathcal{H}}$. Then the *resolvent average*

$$
\left(\sum_{k=1}^{p} \omega_k J_{A_k}\right)^{-1} - \mathrm{Id}_{\mathcal{H}} \tag{2.66}
$$

is maximally monotone. This result was originally established in [Bartz, Bauschke,](#page-127-9) [Moffat and Wang](#page-127-9) [\(2016,](#page-127-9) Proposition 2.7) and derived from Example [2.31](#page-18-0) in [Combettes](#page-132-10) [\(2023,](#page-132-10) Remark 4.10(ii)).

Example 2.33. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be a maximally monotone operator and let V be a closed vector subspace of H . The *partial inverse* of A with respect to V is the operator $A_V: \mathcal{H} \to 2^{\mathcal{H}}$ with graph

$$
\text{gra } A_V = \{ (\text{proj}_V x + \text{proj}_{V^{\perp}} x^*, \text{proj}_V x^* + \text{proj}_{V^{\perp}} x) \mid (x, x^*) \in \text{gra } A \}. \tag{2.67}
$$

This construction was introduced in [Spingarn](#page-142-6) [\(1983\)](#page-142-6), which contains the following (see [Spingarn](#page-142-6) [1983,](#page-142-6) Section 2):

- (i) A_V is maximally monotone.
- (ii) Let $x \in \mathcal{H}$. Then $x \in \text{zer } A_V \Leftrightarrow (\text{proj}_V x, \text{proj}_{V^{\perp}} x) \in \text{gra } A$.

2.4.2. Resolvent

In terms of solving inclusion problems, the resolvent of [\(2.17\)](#page-7-2) is the most important operator attached to a monotone operator A . First, as seen in (2.18) , it can be employed as a device to generate points in the graph of A. Second, as seen in (2.19) , its fixed point set coincides with the set of zeros of A . Third, resolvents provide an effective bridge between the theory of nonexpansive operators and that of monotone operators. This connection goes back to the theory of semigroups of linear nonexpansive operators. The following result, essentially due to [Minty](#page-139-7) [\(1962\)](#page-139-7), establishes such a connection in the nonlinear case. It states in particular that the resolvent of a maximally monotone operator is a firmly nonexpansive operator which is defined everywhere.

Figure 2.3. Illustration of Minty's theorem (Lemma [2.34\)](#page-20-0). From left to right on each row: graph of A , graph of $Id + A$ and graph of J_A . (a) A is not monotone: ran(Id+A) = dom $J_A \neq H$ and J_A is not firmly nonexpansive. (b) A is monotone but not maximally monotone: J_A is firmly nonexpansive but ran(Id+A) = dom $J_A \neq H$. (c) A is maximally monotone: J_A is firmly nonexpansive with ran(Id + A) = $dom J_A = H$.

Lemma 2.34 [\(Bauschke and Combettes](#page-127-6) [2017,](#page-127-6) Proposition 23.8). Let D be a nonempty subset of H, let $T: D \to H$, and set $A = T^{-1} - \text{Id}$. Then the following hold (see Figure [2.3\)](#page-19-0):

- (i) $D = \text{ran}(\text{Id} + A)$ and $T = J_A$.
- (ii) T is firmly nonexpansive if and only if A is monotone.

(iii) T is firmly nonexpansive and $D = H$ if and only if A is maximally monotone.

Here are a few examples of resolvents that will be explicitly needed; see [Bauschke](#page-127-6) [and Combettes\(2017\)](#page-127-6), [Chierchia, Chouzenoux, Combettes and Pesquet](#page-132-11) [\(2016\)](#page-132-11) and [Combettes and Pesquet](#page-133-1) [\(2011\)](#page-133-1) for additional examples with closed-form expressions and, in particular, instances of proximity operators.

Example 2.35 [\(Moreau](#page-139-12) [1965\)](#page-139-12). Let $f \in \Gamma_0(\mathcal{H})$. Then $J_{\partial f} = \text{prox}_f$.

Example 2.36 [\(Moreau](#page-139-13) [1962\)](#page-139-13). Let C be a nonempty closed convex subset of H . Then $J_{N_C} = \text{prox}_{\iota_C} = \text{proj}_C$.

Example 2.37 [\(Bauschke and Combettes](#page-127-6) [2017,](#page-127-6) Proposition 23.18). Let $0 < m \in$ N, let $(\mathcal{H}_i)_{1 \leq i \leq m}$ be real Hilbert spaces, set

$$
\mathcal{H} = \bigoplus_{i=1}^{m} \mathcal{H}_i,
$$
\n(2.68)

and, for every $i \in \{1, ..., m\}$, let $A_i : \mathcal{H}_i \to 2^{\mathcal{H}_i}$ be maximally monotone. Set

$$
A: \mathcal{H} \to 2^{\mathcal{H}}: (x_i)_{1 \le i \le m} \mapsto \underset{1 \le i \le m}{\times} A_i x_i. \tag{2.69}
$$

Then A is maximally monotone (Lemma [2.24\)](#page-16-5) and

$$
J_A: \mathcal{H} \to \mathcal{H}: (x_i)_{1 \le i \le m} \mapsto (J_{A_i} x_i)_{1 \le i \le m}.
$$
 (2.70)

Example 2.38. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, let V be a closed vector subspace of H , and let A_V be the partial inverse of Example [2.33.](#page-18-1) In addition, let $x \in \mathcal{H}$ and $p \in \mathcal{H}$. Then

$$
p = J_{Ay}x \iff \text{proj}_V p + \text{proj}_{V^{\perp}}(x - p) = J_Ax. \tag{2.71}
$$

Proof. This is implicit in [Spingarn](#page-142-6) [\(1983,](#page-142-6) Section 4); see [Alghamdi, Alotaibi,](#page-126-10) [Combettes and Shahzad](#page-126-10) [\(2014,](#page-126-10) Lemma 2.2) for a proof. \Box

Example 2.39 (Combettes and V \tilde{u} **[2014\)](#page-133-11).** As in Lemma [2.25\(](#page-16-6)[ii\)](#page-16-2), $A: \mathcal{H} \rightarrow 2^{\mathcal{H}}$ is maximally monotone, $U \in \mathcal{B}(\mathcal{H})$ is self-adjoint and strongly monotone, and X is the real Hilbert space obtained by endowing H with the scalar product $(x, y) \mapsto \langle Ux | y \rangle$. Then $J_{U^{-1} \circ A} = (U + A)^{-1} \circ U$.

Example 2.40 [\(Combettes](#page-132-10) [2023\)](#page-132-10). Let $L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$ be such that $||L|| \leq 1$, let $B: \mathcal{G} \to 2^{\mathcal{G}}$ be maximally monotone, and consider the resolvent compositions of Example [2.31.](#page-18-0) Then

$$
J_{L\diamond B} = L^* \circ J_B \circ L \quad \text{and} \quad J_{L \bullet B} = \text{Id}_{\mathcal{H}} - L^* \circ L + L^* \circ J_B \circ L. \tag{2.72}
$$

2.4.3. Warped resolvents

A generalization of the notion of a resolvent is the following.

Definition 2.41 [\(Bùi and Combettes](#page-130-16) [2020](#page-130-16)*b***).** Let *D* be a nonempty subset of H , let $U\colon D\to\mathcal{H},$ and let $M\colon\mathcal{H}\to 2^\mathcal{H}$ be such that ran $U\subset\mathop{\rm ran}\nolimits(U+M)$ and $U+M$ is injective. The *warped resolvent* of M with kernel U is $J_M^U = (U + M)^{-1} \circ U : D \to D$.

The properties of warped resolvent generalize those of classical ones. In this respect, here is an extension of [\(2.18\)](#page-7-3)–[\(2.19\)](#page-7-4).

Lemma 2.42. Let D and E be nonempty subsets of H , let $U: D \rightarrow H$, let $C: E \to \mathcal{H}$, and let $W: \mathcal{H} \to 2^{\mathcal{H}}$ be such that ran $U \subset \text{ran}(U + W + C)$ and $U + W + C$ is injective. Then the following hold:

- (i) Let $x \in D$ and $p \in D$. Then $p = J_{W+C}^U x \Leftrightarrow (p, Ux - Up - Cp) \in \text{gra } W$.
- (ii) Fix $J_{W+C}^U = D \cap \text{zer}(W + C)$.

Proof. Note that $J_{W+C}^U: D \to D$ is well defined.

[\(i\)](#page-21-0) $p = J_{W+C}^U x \Leftrightarrow p = (U+W+C)^{-1}(Ux) \Leftrightarrow Ux \in Up+Wp+Cp \Leftrightarrow Ux-Up-Cp \in U$ $Wp.$

[\(ii\)](#page-21-1) Let $x \in \mathcal{H}$. Then [\(i\)](#page-21-0) yields $x = J_{W+C}^U x \Leftrightarrow [x \in D \text{ and } (x, -Cx) \in \text{gra } W] \Leftrightarrow$ [$x \in D$ and $x \in \text{zer}(W + C)$]. \Box

An instance of a warped resolvent with a linear kernel appears in Example [2.39,](#page-20-1) where $D = H$ and $U \in \mathcal{B}(\mathcal{H})$ is a self-adjoint strongly monotone operator. Selfadjoint monotone operators which are not strongly monotone have also been used as kernels; see [Bredies, Chenchene, Lorenz and Naldi](#page-129-12) [\(2022\)](#page-129-12) and [Xue](#page-144-6) [\(2023](#page-144-6)*b*). The next example features a monotone kernel in $\mathcal{B}(\mathcal{H})$ which is not self-adjoint.

Example 2.43. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{G} \to 2^{\mathcal{G}}$ be maximally monotone, and suppose that $0 \neq L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$. Set $\mathbf{X} = \mathcal{H} \oplus \mathcal{G}$ and

$$
\begin{cases} \mathcal{K}: \mathbf{X} \to 2^{\mathbf{X}}: (x, y^*) \mapsto (Ax + L^*y^*) \times (B^{-1}y^* - Lx), \\ U: \mathbf{X} \to \mathbf{X}: (x, y^*) \mapsto (x - L^*y^*, Lx + y^*). \end{cases}
$$
(2.73)

As will be seen in Lemma [3.8,](#page-24-0) $\mathcal K$ is the Kuhn–Tucker operator associated with the problem of finding a zero of $A + L^* \circ B \circ L$. It follows from [\(2.73\)](#page-21-2) that

$$
J_K^U: \mathbf{X} \to \mathbf{X}: (x, y^*) \mapsto (J_A(x - L^* y^*), J_{B^{-1}}(Lx + y^*)), \tag{2.74}
$$

whereas $J_{\mathcal{K}}$ is typically intractable.

The next examples employ nonlinear kernels.

Example 2.44. Let $M: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone and such that zer $M \neq$ \emptyset , let $f: \mathcal{H} \to [-\infty, +\infty]$ be a Legendre function such that dom $M \subset \text{int dom } f$, and set $D = \text{int dom } f$ and $U = \nabla f$. Then it follows from [Bauschke, Borwein](#page-128-7)

[and Combettes](#page-128-7) [\(2003,](#page-128-7) Corollary 3.14(ii)) that J_M^U : $D \rightarrow D$ is a well-defined warped resolvent, called the D -resolvent of M . It is an essential tool in the study of algorithms based on Bregman distances which goes back to [Brègman](#page-129-13) [\(1967\)](#page-129-13), [Censor and Zenios](#page-131-8) [\(1992\)](#page-131-8), [Eckstein](#page-134-9) [\(1993\)](#page-134-9) and [Teboulle](#page-143-12) [\(1992\)](#page-143-12).

Example 2.45. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, and let $f \in \Gamma_0(\mathcal{H})$ be essentially smooth [\(Bauschke, Borwein and Combettes](#page-128-7) [2003\)](#page-128-7). Suppose that $D = (int dom f) \cap dom A$ is a nonempty subset of int dom B, that B is single-valued on int dom B, that ∇f is strictly monotone on D, and that $(\nabla f - B)(D) \subset \text{ran}(\nabla f + A)$. Set $M = A + B$ and $U: D \to \mathcal{H}: x \mapsto \nabla f(x) - Bx$. Then the warped resolvent coincides with the Bregman forward–backward operator $J_M^U = (\nabla f + A)^{-1} \circ (\nabla f - B)$ investigated in [Bùi and Combettes](#page-130-17) [\(2021\)](#page-130-17), where it is shown to capture a construction found in [Renaud and Cohen](#page-141-12) [\(1997\)](#page-141-12) and known as the *auxiliary principle*. In the case when A and B are subdifferentials, J_M^U is the operator studied in [Nguyen](#page-140-8) [\(2017\)](#page-140-8) and, in Euclidean spaces, in [Bauschke, Bolte](#page-128-8) [and Teboulle](#page-128-8) [\(2017\)](#page-128-8). Scenarios in which J_M^U is more manageable than J_M are discussed in [Bauschke](#page-128-8) *et al.* [\(2017\)](#page-128-8), [Bùi and Combettes](#page-130-17) [\(2021\)](#page-130-17), [Lu, Freund and](#page-138-7) [Nesterov](#page-138-7) [\(2018\)](#page-138-7), [Nguyen](#page-140-8) [\(2017\)](#page-140-8), [Renaud and Cohen](#page-141-12) [\(1997\)](#page-141-12) and [Teboulle](#page-143-13) [\(2018\)](#page-143-13).

Example 2.46. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$, let $C: \mathcal{H} \to \mathcal{H}$ be cocoercive, let $Q: \mathcal{H} \to \mathcal{H}$ be monotone and Lipschitzian, and let $\gamma \in [0, +\infty)$. The underlying problem is to find a point in $zer(A + C + Q)$ and we recover the *nonlinear forward–backward operator* of [Giselsson](#page-136-9) [\(2021\)](#page-136-9) as a warped resolvent as follows. Set $M = \gamma(A+C+Q)$, let $K: \mathcal{H} \to \mathcal{H}$ be strongly monotone and Lipschitzian, and set $U = K - \gamma(C + Q)$. Then $J_M^U = (K + \gamma A)^{-1} \circ (K - \gamma (C + Q))$, which is the operator driving the algorithms of [Giselsson](#page-136-9) [\(2021\)](#page-136-9).

Remark 2.47. If *B* is cocoercive and $f = || \cdot ||^2 / 2$ in Example [2.45,](#page-22-0) or if $K = Id$ and $Q = 0$ and $C = B$ in Example [2.46,](#page-22-1) then $J_M^{U} = J_{\gamma A} \circ (\text{Id} - \gamma B)$. This operator will arise in the forward–backward algorithm of Section [8.](#page-77-0)

Lemma 2.48. Let $Q: \mathcal{H} \to \mathcal{H}$ be Lipschitzian with constant $\beta \in [0, +\infty)$, let $K: \mathcal{H} \to \mathcal{H}$ be strongly monotone with constant $\alpha \in [0, +\infty)$, let $\varepsilon \in [0, \alpha]$, and set $U = K - \gamma Q$. Then the following hold:

- (i) Let $\gamma \in [0, (\alpha \varepsilon)/\beta]$. Then U is ε -strongly monotone [\(Bùi and Combettes](#page-130-16) [2020](#page-130-16)*b*, Lemma 5.1(i)).
- (ii) Suppose that $\alpha = 1$ and $K = Id$, and let $\gamma \in [0, (1 \varepsilon)/\beta]$. Then U is cocoercive with constant $1/(2-\varepsilon)$ [\(Bùi and Combettes](#page-130-16) [2020](#page-130-16)*b*, Lemma 5.1(ii)).
- (iii) Suppose that $\alpha = 1$, $K = \text{Id}$, and Q is $1/\beta$ -cocoercive, and let $\gamma \in [0, 2/\beta]$. Then U is $\gamma \beta / 2$ -averaged, hence nonexpansive [\(Combettes](#page-132-6) [2004,](#page-132-6) Lemma 2.3).

2.4.4. Topological properties

We record key properties of the graphs of monotone operators.

Lemma 2.49 [\(Bauschke and Combettes](#page-127-6) [2017,](#page-127-6) Proposition 20.38(ii)). Let M : $\mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone. Then gra *M* is sequentially closed in $\mathcal{H}^{\text{weak}} \times$ $\mathcal{H}^{\text{strong}}$, that is, for every sequence $(x_n, x_n^*)_{n \in \mathbb{N}}$ in gra M and every $(x, x^*) \in \mathcal{H} \times \mathcal{H}$, if $x_n \to x$ and $x_n^* \to x^*$, then $(x, x^*) \in \text{gra } M$.

Lemma 2.50 [\(Bauschke and Combettes](#page-127-6) [2017,](#page-127-6) Corollary 26.6). Let A : $\mathcal{H} \rightarrow 2^{\mathcal{H}}$ and $B: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, let $(x_n, x_n^*)_{n \in \mathbb{N}}$ be a sequence in gra A, let $(y_n, y_n^*)_{n \in \mathbb{N}}$ be a sequence in gra B, let $x \in \mathcal{H}$, and let $x^* \in \mathcal{H}$. Suppose that

$$
x_n \to x
$$
, $x_n^* \to x^*$, $x_n - y_n \to 0$ and $x_n^* + y_n^* \to 0$. (2.75)

Then $x \in \text{zer}(A + B)$, $-x^* \in \text{zer}(-A^{-1} \circ (-Id) + B^{-1})$, $(x, x^*) \in \text{gra } A$ and $(x, -x^*) \in$ gra B .

2.4.5. Subdifferentials

The subdifferential operator of Example [2.12](#page-13-0) is an essential tool in variational analysis.

Lemma 2.51 [\(Bauschke and Combettes](#page-127-6) [2017,](#page-127-6) Proposition 16.6 and Theorem 16.47(i)). Let $f \in \Gamma_0(\mathcal{H})$, $g \in \Gamma_0(\mathcal{G})$ and $L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$ be such that $(L(\text{dom } f)) \cap$ dom $g \neq \emptyset$. Then the following hold:

- (i) $\text{zer}(\partial f + L^* \circ (\partial g) \circ L) \subset \text{zer} \partial (f + g \circ L) = \text{Argmin} (f + g \circ L).$
- (ii) Suppose that one of the following is satisfied:
	- (a) $0 \in \text{sri}(L(\text{dom } f) \text{dom } g)$.
	- (b) $L(\text{dom } f) \text{dom } g$ is a closed vector subspace of \mathcal{G} .
	- (c) dom $g = G$.
	- (d) G is finite-dimensional and (ri $L(\text{dom } f)$) \cap (ri dom g) $\neq \emptyset$.

Then $\partial(f + g \circ L) = \partial f + L^* \circ (\partial g) \circ L$.

3. Structured monotone inclusions

Our master problem is the following two-operator inclusion.

Problem 3.1. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone. The objective is to

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + Bx$. (3.1)

3.1. Two-operator formulations

We provide problem formulations which correspond to specific choices of the operators A and B in Problem [3.1](#page-23-1) from the examples of Section [2.3.](#page-12-2)

Problem 3.2. In Problem [3.1,](#page-23-1) let $f \in \Gamma_0(\mathcal{H})$, set $A = \partial f$, and suppose that B is at most single-valued. Then [\(3.1\)](#page-23-2) reduces to the variational inequality problem [\(Lions](#page-138-5) [1969\)](#page-138-5)

find
$$
x \in \mathcal{H}
$$
 such that $(\forall y \in \mathcal{H}) \langle x - y | Bx \rangle + f(x) \le f(y)$. (3.2)

Problem 3.3. In Problem [3.2,](#page-23-3) let C be a nonempty closed convex subset of H and set $f = \iota_C$. Then [\(3.2\)](#page-24-1) reduces to the standard variational inequality problem [\(Fichera](#page-135-6) [1963,](#page-135-6) [Kinderlehrer and Stampacchia](#page-137-13) [1980\)](#page-137-13)

find
$$
x \in C
$$
 such that $(\forall y \in C) \langle x - y | Bx \rangle \le 0$. (3.3)

Problem 3.4. In Problem [3.3,](#page-24-2) suppose that C is a cone with dual cone C^{\oplus} . Then [\(3.3\)](#page-24-3) reduces to the *complementarity problem* [\(Facchinei and Pang](#page-135-0) [2003\)](#page-135-0)

find
$$
x \in C
$$
 such that $x \perp Bx$ and $Bx \in C^{\oplus}$. (3.4)

Problem 3.5. In Problem [3.1,](#page-23-1) let $f \in \Gamma_0(\mathcal{H})$ and $g \in \Gamma_0(\mathcal{H})$, and set $A = \partial f$ and $B = \partial g$. Suppose that one of the following holds:

- (i) $0 \in \text{sri}(\text{dom } f \text{dom } g)$.
- (ii) $g: \mathcal{H} \to \mathbb{R}$ is differentiable.

Then the objective is to

$$
\underset{x \in \mathcal{H}}{\text{minimize}} \quad f(x) + g(x). \tag{3.5}
$$

Problem 3.6. In Problem [3.5,](#page-24-4) let C be a nonempty closed convex subset of H and set $f = \iota_C$. Suppose that one of the following holds:

- (i) $0 \in \text{sri}(C \text{dom } g)$.
- (ii) $g: \mathcal{H} \to \mathbb{R}$ is differentiable.

Then the objective is to

$$
\underset{x \in C}{\text{minimize}} g(x). \tag{3.6}
$$

3.2. Composite problems

We start by presenting a duality framework for monotone inclusions introduced in [Pennanen](#page-140-7) [\(2000\)](#page-140-7) and [Robinson](#page-141-13) [\(1999,](#page-141-13) [2001\)](#page-141-14); for special cases, see [Alduncin](#page-126-11) [\(2005\)](#page-126-11), [Attouch and Théra](#page-127-10) [\(1996\)](#page-127-10), [Eckstein and Ferris](#page-134-10) [\(1999\)](#page-134-10), [Fukushima](#page-135-3) [\(1996\)](#page-135-3), [Gabay](#page-135-7) [\(1983\)](#page-135-7), [Mercier](#page-139-1) [\(1980\)](#page-139-1), [Mosco](#page-139-14) [\(1972\)](#page-139-14) and [Robinson](#page-141-15) [\(1998\)](#page-141-15).

Problem 3.7. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{G} \to 2^{\mathcal{G}}$ be maximally monotone, and let $L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$. The objective is to solve the primal inclusion

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + L^*(B(Lx))$ (3.7)

together with the dual inclusion

find
$$
y^* \in \mathcal{G}
$$
 such that $0 \in -L(A^{-1}(-L^*y^*)) + B^{-1}y^*$. (3.8)

Lemma 3.8 [\(Briceño-Arias and Combettes](#page-129-5) [2011\)](#page-129-5). In the setting of Problem[3.7,](#page-24-5) let $X = H \oplus G$, let Z and Z^{*} be the sets of solutions to [\(3.7\)](#page-24-6) and [\(3.8\)](#page-24-7), respectively, and set

$$
\begin{cases}\nM: \mathbf{X} \to 2^{\mathbf{X}}: (x, y^*) \mapsto Ax \times B^{-1}y^*, \\
S: \mathbf{X} \to \mathbf{X}: (x, y^*) \mapsto (L^*y^*, -Lx).\n\end{cases}
$$
\n(3.9)

Define the *Kuhn–Tucker operator* of Problem [3.7](#page-24-5) as

$$
\mathcal{K} = M + S \tag{3.10}
$$

and the set of *Kuhn–Tucker points* as zer K . Then the following hold:

- (i) M is maximally monotone.
- (ii) $S \in \mathcal{B}(\mathbf{X})$ is skew and maximally monotone, with $||S|| = ||L||$.
- (iii) κ is maximally monotone.
- (iv) zer K is a closed convex subset of $Z \times Z^*$ in X.
- (v) $Z \neq \emptyset \Leftrightarrow$ zer $K \neq \emptyset \Leftrightarrow Z^* \neq \emptyset$ (see also [Eckstein and Ferris](#page-134-10) [1999,](#page-134-10) [Pennanen](#page-140-7) [2000,](#page-140-7) [Robinson](#page-141-13) [1999\)](#page-141-13).

The best known instance for Problem [3.7](#page-24-5) is the classical Fenchel–Rockafellar duality framework [\(Rockafellar](#page-141-16) [1967\)](#page-141-16).

Problem 3.9. Let $f \in \Gamma_0(\mathcal{H})$, $g \in \Gamma_0(\mathcal{G})$ and $L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$ be such that $0 \in \text{sri}(L(\text{dom } f) - \text{dom } g).$ (3.11)

Set $A = \partial f$ and $B = \partial g$ in Problem [3.7.](#page-24-5) Then it follows from Lemma [2.51](#page-23-4) that [\(3.7\)](#page-24-6) is the primal problem

$$
\underset{x \in \mathcal{H}}{\text{minimize}} \quad f(x) + g(Lx),\tag{3.12}
$$

[\(3.8\)](#page-24-7) is the *Fenchel–Rockafellar dual* problem

$$
\underset{y^* \in \mathcal{G}}{\text{minimize}} \quad f^*(-L^*y^*) + g^*(y^*),\tag{3.13}
$$

and [\(3.10\)](#page-25-0) yields the Kuhn–Tucker operator

$$
\mathcal{K}: (x, y^*) \mapsto (\partial f(x) + L^* y^*) \times (-Lx + \partial g^*(y^*)). \tag{3.14}
$$

Problem 3.10. Let V be a closed vector subspace of H and let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone. Then, in the case when $G = H$ and $L = Id$, the Kuhn–Tucker operator [\(3.10\)](#page-25-0) associated with the operators N_V and A is

$$
\mathcal{K}: \mathcal{H} \oplus \mathcal{H} \to 2^{\mathcal{H} \oplus \mathcal{H}}: (x, x^*) \mapsto (N_V x + x^*) \times (A^{-1} x^* - x). \tag{3.15}
$$

In view of Example [2.15,](#page-13-2) the problem of finding a zero of the maximally monotone operator κ reduces to

find
$$
x \in V
$$
 and $x^* \in V^{\perp}$ such that $x^* \in Ax$. (3.16)

This formulation was first considered by [Spingarn](#page-142-6) [\(1983\)](#page-142-6).

An extension of Problem [3.7](#page-24-5) involving several linearly composed terms is the following.

Problem 3.11. Let $0 < p \in \mathbb{N}$, let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, and, for every $k \in \{1 \ldots, p\}$, let \mathcal{G}_k be a real Hilbert space, let $B_k : \mathcal{G}_k \to 2^{\mathcal{G}_k}$ be maximally monotone, and let $L_k \in \mathcal{B}(\mathcal{H}, \mathcal{G}_k)$. The objective is to solve the primal inclusion

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + \sum_{k=1}^{p} L_k^*(B_k(L_k x))$ (3.17)

together with the dual inclusion

find
$$
y_1^* \in G_1, ..., y_p^* \in G_p
$$
 such that
\n
$$
\left(\exists x \in A^{-1}\left(-\sum_{k=1}^p L_k^* y_k^*\right)\right) (\forall k \in \{1, ..., p\}) L_k x \in B_k^{-1} y_k^*.
$$
\n(3.18)

Lemma 3.12. In the setting of Problem [3.11,](#page-26-0) set $X = H \oplus G_1 \oplus \cdots \oplus G_p$ and let Z and Z^* be the sets of solutions to [\(3.17\)](#page-26-1) and [\(3.18\)](#page-26-2), respectively. Define the *Kuhn–Tucker operator* of Problem [3.11](#page-26-0) as

$$
\mathcal{K}: \mathbf{X} \to 2^{\mathbf{X}}: (x, y_1^*, \dots, y_p^*) \mapsto
$$
\n
$$
\left(Ax + \sum_{k=1}^p L_k^* y_k^*\right) \times \left(-L_1 x + B_1^{-1} y_1^*\right) \times \dots \times \left(-L_p x + B_p^{-1} y_p^*\right) \tag{3.19}
$$

and the set of *Kuhn–Tucker points* as zer K . Then the following hold:

- (i) κ is maximally monotone.
- (ii) zer K is a closed convex subset of $Z \times Z^*$ in X.
- (iii) $Z \neq \emptyset \Leftrightarrow \text{zer } \mathcal{K} \neq \emptyset \Leftrightarrow Z^* \neq \emptyset$.

Proof. The proof is similar to that of Lemma [3.8.](#page-24-0)

An alternative angle on Problem [3.9](#page-25-1) is provided by the Lagrangian approach of Example [2.22.](#page-15-2) Set $f: \mathcal{H} \oplus \mathcal{G} \rightarrow]-\infty, +\infty] : x = (x, y) \mapsto f(x) + g(y),$ $\mathbf{L}: \mathcal{H} \oplus \mathcal{G} \to \mathcal{G}: (x, y) \mapsto Lx - y$ and $\mathbf{X} = \mathcal{H} \oplus \mathcal{G} \oplus \mathcal{G}$. Then the primal problem [\(3.12\)](#page-25-2) is equivalent to

$$
\underset{x \in \ker L}{\text{minimize}} \quad f(x) \tag{3.20}
$$

and its standard perturbation function is [\(Rockafellar](#page-141-11) [1974,](#page-141-11) Example 4'; see also [Bauschke and Combettes](#page-127-6) [2017,](#page-127-6) Proposition 19.21)

$$
F: \mathbf{X} \to]-\infty, +\infty] : (x, v) \mapsto f(x) + \iota_{\{0\}}(Lx + v). \tag{3.21}
$$

We derive from (2.55) that the associated Lagrangian is

$$
\mathcal{L}_F: \mathbf{X} \to]-\infty, +\infty] : (x, v^*) \mapsto f(x) + \langle Lx | v^* \rangle, \tag{3.22}
$$

 \Box

from (2.56) that the associated dual problem is (3.13) , and from (2.57) that the associated saddle operator is

$$
S_F: \mathbf{X} \to 2^{\mathbf{X}}: (x, v^*) \mapsto (\partial f(x) + L^* v^*) \times \{-Lx\},\tag{3.23}
$$

that is,

$$
\mathcal{S}_F: \quad \mathbf{X} \quad \to \quad 2^{\mathbf{X}} \quad (x, y, v^*) \quad \mapsto \quad (\partial f(x) + L^* v^*) \times (\partial g(y) - v^*) \times \{-Lx + y\}.\tag{3.24}
$$

We saw in Example [2.22](#page-15-2) that, if $(x, y, v^*) \in \text{zer} \mathcal{S}_F$, then x solves the primal problem (3.12) and v^* solves the dual problem (3.13) . A version of this result for Problem [3.7](#page-24-5) is the following where, although there is no notion of a Lagrangian, we can introduce a saddle operator.

Lemma 3.13. In the setting of Problem [3.7,](#page-24-5) set $X = H \oplus G \oplus G$ and let Z and Z^* be the sets of solutions to [\(3.7\)](#page-24-6) and [\(3.8\)](#page-24-7), respectively. Define the Kuhn–Tucker operator κ as in [\(3.10\)](#page-25-0) and define the *saddle operator* of Problem [3.7](#page-24-5) as

$$
\mathcal{S}: \quad \mathbf{X} \quad \to \quad 2^{\mathbf{X}}(x, y, v^*) \quad \mapsto \quad (Ax + L^*v^*) \times (By - v^*) \times \{-Lx + y\}.
$$

Then the following hold:

- (i) \mathcal{S} is maximally monotone.
- (ii) zer S is closed and convex.
- (iii) Suppose that $(x, y, v^*) \in \text{zer } S$. Then $(x, v^*) \in \text{zer } K \subset Z \times Z^*$.
- (iv) $Z^* \neq \emptyset \Leftrightarrow \text{zer } S \neq \emptyset \Leftrightarrow \text{zer } K \neq \emptyset \Leftrightarrow Z \neq \emptyset.$

Proof. This is a special case of [Bùi and Combettes](#page-131-6) [\(2022](#page-131-6)*b*, Proposition 1(i)– $(v)(a)$). \Box

3.3. Examples of embeddings in Framework [1.2](#page-4-0)

Example 3.14. Suppose that it is computationally feasible solve Problem [1.1](#page-1-1) directly in the original space H . Then an embedding of Problem [1.1](#page-1-1) is just $(H, M, Id).$

Example 3.15. Let $M: \mathcal{H} \to 2^{\mathcal{H}}$ be a maximally monotone operator, let $U \in$ $B(H)$ be a self-adjoint strongly monotone operator, let **X** be the real Hilbert space obtained by endowing H with the scalar product $(x, y) \mapsto \langle Ux | y \rangle$, let $\mathcal{M} =$ $U^{-1} \circ M$, and set $\mathcal{T} =$ Id. Then it follows from Lemma [2.25](#page-16-6)[\(i\)](#page-16-1)–[\(ii\)](#page-16-2) that $(\mathbf{X}, \mathcal{M}, \mathcal{T})$ is an embedding of Problem [1.1.](#page-1-1)

Example 3.16. Let $\alpha \in [0, 1]$ and let $T: \mathcal{H} \to \mathcal{H}$ be α -averaged. In Problem [1.1,](#page-1-1) suppose that $M = Id - T$ (see Example [2.4\)](#page-12-0) and set

$$
\mathbf{X} = \mathcal{H}, \quad \mathcal{M} = \left(\mathrm{Id} + \frac{1}{2\alpha}(T - \mathrm{Id})\right)^{-1} - \mathrm{Id} \quad \text{and} \quad \mathcal{T} = \mathrm{Id}.
$$
 (3.26)

Then $(\mathbf{X}, \mathcal{M}, \mathcal{T})$ is an embedding of Problem [1.1.](#page-1-1) Indeed, since Id + $\alpha^{-1}(T - \text{Id})$ is nonexpansive, we derive from [Bauschke and Combettes](#page-127-6) [\(2017,](#page-127-6) Proposition 4.4) that Id + $(2\alpha)^{-1}(T - \text{Id})$ is firmly nonexpansive, and hence from Lemma [2.34](#page-20-0)[\(iii\)](#page-20-2) that M is maximally monotone, with zer $M = \text{zer } M = \text{Fix } T$.

Example 3.17. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, and let $\gamma \in [0, +\infty[$. Let

$$
\mathbf{X} = \mathcal{H}, \quad \mathbf{M} = (J_{\gamma A} \circ (2J_{\gamma B} - \text{Id}) + \text{Id} - J_{\gamma B})^{-1} - \text{Id} \quad \text{and} \quad \mathbf{T} = J_{\gamma B}. \tag{3.27}
$$

Then it follows from [Eckstein and Bertsekas](#page-134-1) [\(1992,](#page-134-1) Section 4) that $(X, \mathcal{M}, \mathcal{T})$ is an embedding of Problem [3.1.](#page-23-1) In this setting, we actually have \mathcal{T} (zer \mathcal{M}) = zer M [\(Combettes](#page-132-6) [2004,](#page-132-6) Lemma 2.6(iii)).

Example 3.18. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone. Let $\mathbf{X} = \mathcal{H} \oplus \mathcal{H}, \ \mathcal{M} : \mathbf{X} \to 2^{\mathbf{X}} : (x, x^*) \mapsto (Ax + x^*) \times (-x + B^{-1}x^*)$ and $\mathcal{T} : \mathbf{X} \to \mathbf{X}$ $\mathcal{H}: (x, x^*) \mapsto x$. Then applying Lemma [3.8](#page-24-0) with $\mathcal{G} = \mathcal{H}$ and $L = \text{Id}$ shows that (X, M, T) is an embedding of Problem [3.1.](#page-23-1) This embedding is implicitly present in the projective splitting algorithm of [Eckstein and Svaiter](#page-134-11) [\(2008\)](#page-134-11), which is therefore an instance of Framework [1.2.](#page-4-0)

We now discuss structured inclusion problems that offer greater modelling flexibility by involving three or more operators. The principle of a splitting algorithm, which is to involve each operator individually, faces a serious challenge in the presence of such formulations. Indeed, since inclusion is a binary relation, for reasons discussed in [Briceño-Arias and Combettes](#page-129-5) [\(2011\)](#page-129-5) and [Combettes](#page-132-12) [\(2013](#page-132-12)*a*), and analysed in more depth in [Ryu](#page-142-7) [\(2020\)](#page-142-7), it is not possible to split problems that involve more than two set-valued operators. A purpose of Framework [1.2](#page-4-0) is to circumvent this fundamental limitation by seeking more tractable reformulations in bigger spaces.

Example 3.19. Let $0 < p \in \mathbb{N}$ and, for every $k \in \{1, ..., p\}$, let $A_k : \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone. The problem is to

find
$$
x \in \mathcal{H}
$$
 such that $0 \in \sum_{k=1}^{p} A_k x$. (3.28)

Let **X** be the *p*-fold Hilbert direct sum \mathcal{H}^p and set

$$
\begin{cases}\nV = \{(x_1, \ldots, x_p) \in \mathbf{X} \mid x_1 = \cdots = x_p\}, \\
A: \mathbf{X} \to 2^{\mathbf{X}}: (x_1, \ldots, x_p) \mapsto A_1 x_1 \times \cdots \times A_p x_p, \\
\mathcal{M} = A + N_V, \\
\mathcal{T}: \mathbf{X} \to \mathcal{H}: (x_1, \ldots, x_p) \mapsto x_1.\n\end{cases}
$$
\n(3.29)

Then

$$
V^{\perp} = \left\{ (x_1^*, \dots, x_p^*) \in \mathbf{X} \mid \sum_{k=1}^p x_k^* = 0 \right\},\tag{3.30}
$$

and it follows from Example [2.15](#page-13-2) that $(X, \mathcal{M}, \mathcal{T})$ is an embedding of [\(3.28\)](#page-28-0). This setting to split the sum of $p > 2$ monotone operators was introduced by [Spingarn](#page-142-6) [\(1983,](#page-142-6) Section 5); see also [Gol'shtein](#page-136-10) [\(1987\)](#page-136-10). It reduces the p -operator problem [\(3.28\)](#page-28-0) to the two-operator inclusion $\mathbf{0} \in Ax + N_Vx$. The idea of rephrasing multioperator problems in product spaces finds its roots in convex feasibility problems [\(Pierra](#page-140-9) [1976,](#page-140-9) [1984\)](#page-140-10), where the problem of finding a point in the intersection $\bigcap_{k=1}^p C_k$ of closed convex subsets $(C_k)_{1 \leq k \leq p}$ of H is associated with that of finding a point in $C \cap V$ in **X**, where $C = C_1 \times \cdots \times C_n$.

Example 3.20. In the setting of Problem [3.7,](#page-24-5) set $X = H \oplus G$, define M and S as in [\(3.9\)](#page-25-4), let $\mathcal{K} = M + S$ be the Kuhn–Tucker operator of [\(3.10\)](#page-25-0), and let $\mathcal{T} : X \rightarrow$ $H: (x, y^*) \mapsto x$. Then, in view of Lemma [3.8](#page-24-0)[\(iv\)](#page-25-5), $(X, \mathcal{K}, \mathcal{T})$ is an embedding of [\(3.7\)](#page-24-6). This embedding, which underlies the *monotone+skew* framework of [Briceño-Arias and Combettes](#page-129-5) [\(2011\)](#page-129-5), reduces Problem [3.7,](#page-24-5) which involves three operators in the primal space H (namely, A, B and L), to a problem in **X** that involves the two operators M and S .

Example 3.21. In the setting of Problem [3.11,](#page-26-0) set $X = H \oplus G_1 \oplus \cdots \oplus G_p$, let K be the Kuhn–Tucker operator of [\(3.19\)](#page-26-3), and let

$$
\mathcal{T}: \mathbf{X} \to \mathcal{H}: (x, y_1^*, \dots, y_p^*) \mapsto x. \tag{3.31}
$$

Then it follows from Lemma [3.12](#page-26-4)[\(ii\)](#page-26-5) that (X, K, T) is an embedding of [\(3.17\)](#page-26-1).

Next, we consider an embedding for strongly monotone problems.

Example 3.22. Let $\rho \in]0, +\infty[$, let $0 < p \in \mathbb{N}$, let $z \in \mathcal{H}$, and let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone. For every $k \in \{1, ..., p\}$, let $B_k: \mathcal{G}_k \to 2^{\mathcal{G}_k}$ and $D_k: \mathcal{G}_k \to 2^{\mathcal{G}_k}$ be maximally monotone, and suppose that $0 \neq L_k \in \mathcal{B}(\mathcal{H}, \mathcal{G}_k)$. The problem is to

find
$$
x \in \mathcal{H}
$$
 such that $z \in Ax + \sum_{k=1}^{p} L_k^*((B_k \square D_k)(L_k x)) + \rho x.$ (3.32)

Let $\mathbf{X} = \mathcal{G}_1 \oplus \cdots \oplus \mathcal{G}_n$, let

$$
\mathcal{M}: \qquad \mathbf{X} \qquad \to \ 2^{\mathbf{X}} \\
(y_1^*, \ldots, y_p^*) \; \mapsto \; \left(-L_1 \left(J_{A/\rho} \left(\frac{1}{\rho} \left(z - \sum_{k=1}^p L_k^* y_k^* \right) \right) \right) + B_1^{-1} y_1^* + D_1^{-1} y_1^* \right) \\
\times \cdots \times \left(-L_p \left(J_{A/\rho} \left(\frac{1}{\rho} \left(z - \sum_{k=1}^p L_k^* y_k^* \right) \right) \right) + B_p^{-1} y_p^* + D_p^{-1} y_p^* \right), \ (3.33)
$$

and let

$$
\mathcal{T}: \mathbf{X} \to \mathcal{H}: (y_1^*, \dots, y_p^*) \mapsto J_{A/\rho}\left(\frac{1}{\rho}\left(z - \sum_{k=1}^p L_k^* y_k^*\right)\right). \tag{3.34}
$$

Then it follows from Combettes and V \tilde{u} [\(2014,](#page-133-11) Proposition 5.2(iii)) that $(\mathbf{X}, \mathbf{M}, \mathcal{T})$ is an embedding of [\(3.32\)](#page-29-0).

Our last example concerns an embedding based on a saddle operator.

Example 3.23. In the setting of Problem [3.7,](#page-24-5) set $X = H \oplus G \oplus G$, let S be the saddle operator of [\(3.25\)](#page-27-0), and let $\mathcal{T}: \mathbf{X} \to \mathcal{H}: (x, y, v^*) \mapsto x$. Then it follows from Lemma [3.13\(](#page-27-1)[iii\)](#page-27-2) that (X, S, T) is an embedding of [\(3.7\)](#page-24-6).

Additional examples of embeddings will be provided by Examples [7.9,](#page-74-0) [9.8](#page-111-0) and [10.4.](#page-119-0)

4. Two geometric convergence principles

4.1. Overview

The methodology of Framework [1.2](#page-4-0) is to identify a target set Z in a suitable Hilbert space in such a way that every point in Z yields a solution to the original problem of interest. The algorithms we shall consider are Fejérian in the sense that every iteration brings the current iterate closer to every point in Z.

4.2. Fejér monotone scheme

Let us first recall some basic facts about weak and strong convergence in Hilbert spaces.

Lemma 4.1 [\(Bauschke and Combettes](#page-127-6) [2017,](#page-127-6) Section 2.5). Let $(x_n)_{n \in \mathbb{N}}$ be a sequence in H and let $x \in H$. Then the following hold:

- (i) Let Z be a nonempty subset of H. Suppose that $\mathfrak{W}(x_n)_{n\in\mathbb{N}}\subset\mathbb{Z}$ and that, for every $z \in Z$, $(\Vert x_n - z \Vert)_{n \in \mathbb{N}}$ converges. Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z.
- (ii) $x_n \to x \Leftrightarrow [(x_n)_{n \in \mathbb{N}}]$ is bounded and $\mathfrak{W}(x_n)_{n \in \mathbb{N}} = \{x\}$.
- (iii) $x_n \to x \Leftrightarrow [x_n \to x \text{ and } \overline{\lim} ||x_n|| \le ||x||].$

Theorem 4.2. Let Z be a nonempty closed convex subset of H, let $(\lambda_n)_{n\in\mathbb{N}}$ be a sequence of relaxation parameters in [0, 2[, and let $x_0 \in \mathcal{H}$. Iterate (see Figure [4.1\)](#page-32-0)

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nH_n \text{ is a closed half-space such that } Z \subset H_n \\
p_n = \text{proj}_{H_n} x_n \\
x_{n+1} = x_n + \lambda_n (p_n - x_n).\n\end{cases}
$$
\n(4.1)

Then the following hold:

- (i) Fejér monotonicity: $(\forall z \in Z)(\forall n \in \mathbb{N}) ||x_{n+1} - z|| \le ||x_n - z||$.
- (ii) $\sum_{n \in \mathbb{N}} \lambda_n (2 - \lambda_n) ||p_n - x_n||^2 < +\infty.$

518 P. L. Combettes

(iii) Suppose that $\sup_{n \in \mathbb{N}} \lambda_n < 2$. Then $\sum_{n \in \mathbb{N}} ||x_{n+1} - x_n||^2 < +\infty$.

(iv) Suppose that $\mathfrak{W}(x_n)_{n \in \mathbb{N}} \subset \mathbb{Z}$. Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z.

Proof. Let $z \in \mathbb{Z}$. Then, for every $n \in \mathbb{N}$, $H_n = \{u \in \mathcal{H} \mid \langle u - p_n | x_n - p_n \rangle \leq 0\}$ and, since $z \in H_n$, [\(4.1\)](#page-30-1) yields

$$
||x_{n+1} - z||^2 = ||x_n - z||^2 + 2\lambda_n \langle x_n - z | p_n - x_n \rangle + \lambda_n^2 ||p_n - x_n||^2
$$

= $||x_n - z||^2 - \lambda_n (2 - \lambda_n) ||p_n - x_n||^2 + 2\lambda_n \langle z - p_n | x_n - p_n \rangle$
 $\le ||x_n - z||^2 - \lambda_n (2 - \lambda_n) ||p_n - x_n||^2$ (4.2)

$$
= ||x_n - z||^2 - \frac{2 - \lambda_n}{\lambda_n} ||x_{n+1} - x_n||^2
$$
\n(4.3)

$$
\leq \|x_n - z\|^2. \tag{4.4}
$$

[\(i\)](#page-30-2) See [\(4.4\)](#page-31-0).

[\(ii\)](#page-30-3) Fix $N \in \mathbb{N}$. Then [\(4.2\)](#page-31-1) yields

$$
\sum_{n=0}^{N} \lambda_n (2 - \lambda_n) \|p_n - x_n\|^2 \le \|x_0 - z\|^2 \tag{4.5}
$$

and we conclude by letting $N \rightarrow +\infty$.

 $(ii) \Rightarrow (iii)$ $(ii) \Rightarrow (iii)$ $(ii) \Rightarrow (iii)$ This follows from [\(4.3\)](#page-31-3).

[\(iv\)](#page-31-4) In view of [\(i\)](#page-30-2), $(\Vert x_n - z \Vert)_{n \in \mathbb{N}}$ converges. The claim therefore follows from Lemma [4.1](#page-30-4)[\(i\)](#page-30-5). \Box

Remark 4.3. [Fejér](#page-135-8) [\(1922\)](#page-135-8) studied the following problem: given a nonempty closed set $Z \subset \mathbb{R}^N$ and a point $y \notin Z$, can one find a point $x \in \mathbb{R}^N$ such that

$$
(\forall z \in Z) \quad ||x - z|| < ||y - z||. \tag{4.6}
$$

This led [Motzkin and Schoenberg](#page-139-15) [\(1954\)](#page-139-15) to adopt the terminology *Fejér monotone* to describe sequences satisfying property [\(i\)](#page-30-2) in Theorem [4.2.](#page-30-6) In their paper (see also [Agmon](#page-126-12) [1954\)](#page-126-12), an algorithm was developed to solve systems of linear inequalities in $\mathbb{R}^{\overline{N}}$ by successive projections onto the half-spaces defining the polyhedral solution set Z, and Fejér monotonicity was shown to be an adequate tool to study the convergence of this algorithm. Further analysis of Fejér monotonicity was proposed in [Brègman](#page-129-14) [\(1965\)](#page-129-14), [Eremin](#page-135-9) [\(1968](#page-135-9)*a*,*[b](#page-135-10)*) and [Raik](#page-141-17) [\(1967,](#page-141-17) [1969\)](#page-141-18), and nowadays it constitutes a central tool to analyse the asymptotic behaviour of various algorithms [\(Bauschke and Combettes](#page-127-6) [2017\)](#page-127-6).

Remark 4.4. In general, the convergence of $(x_n)_{n \in \mathbb{N}}$ to $x \in \mathbb{Z}$ in Theorem [4.2](#page-30-6)[\(iv\)](#page-31-4) is only weak and, even if it were strong, there exists no rate of convergence on $(||x_n - x||)_{n \in \mathbb{N}}$, even in Euclidean spaces [\(Bauschke, Deutsch and Hundal](#page-128-9) [2009,](#page-128-9) [Gubin, Polyak and Raik](#page-136-11) [1967,](#page-136-11) [Youla](#page-144-12) [1987\)](#page-144-12). In particular, achieving a linear rate of

Figure 4.1. Iteration *n* of the Fejérian algorithm (4.1) .

convergence, that is, securing the existence of $\kappa \in [0, +\infty[$ and $\rho \in [0, 1]$ such that

$$
(\forall n \in \mathbb{N}) \quad ||x_n - x|| \le \kappa \rho^n,\tag{4.7}
$$

requires stringent additional assumptions on the problem. In our inclusion context, a typical assumption is strong monotonicity; see [Bauschke and Combettes](#page-127-6) [\(2017,](#page-127-6) Proposition 26.16) for an example. In the broader context of Theorem [4.2\(](#page-30-6)[i\)](#page-30-2), it is clear that $(d_C(x_n))_{n\in\mathbb{N}}$ decreases and that, for every $n \in \mathbb{N}$ and $m \in \mathbb{N}$, $||x_n - x_{n+m}|| \le ||x_n - \text{proj}_C x_n|| + ||x_{n+m} - \text{proj}_C x_n|| \le 2d_C(x_n)$. Hence, [\(4.7\)](#page-32-1) will hold with $\kappa = 2d_C(x_0)$ if the decreasing property can be strengthened to ($\forall n \in \mathbb{N}$) $d_C(x_{n+1}) \leq \rho d_C(x_n)$.

Remark 4.5. The implementation of [\(4.1\)](#page-30-1) is said to be *unrelaxed* if ($\forall n \in \mathbb{N}$) $\lambda_n = 1$.

4.3. Haugazeau-like scheme

Theorem [4.2](#page-30-6) guarantees only weak convergence to an unspecified point in Z and, as will be seen on several occasions later, strong convergence fails in general (many of these examples will be based on a scenario of [Hundal](#page-137-14) [\(2004\)](#page-137-14) concerning the method of alternating projections). However, in some infinite-dimensional applications in areas such as inverse problems, control, mechanics, PDEs, optics and analogue computing, weak convergence does not offer sufficient guarantees and strong convergence is required. The geometric approach described in this section emanates from ideas found in the work of [Haugazeau](#page-136-12) [\(1967,](#page-136-12) [1968\)](#page-136-13) on the convex feasibility problem. It will provide strong convergence to a specific point in Z, namely the projection of the initial point onto Z. This means that the resulting algorithm is also of interest, even in Euclidean spaces, as a best approximation method.

The following technical fact from [Haugazeau](#page-136-13) [\(1968,](#page-136-13) Théorème 3-1) will be employed repeatedly; see also [Bauschke and Combettes](#page-127-6) [\(2017,](#page-127-6) Corollary 29.25).

Lemma 4.6 [\(Haugazeau](#page-136-13) [1968\)](#page-136-13). Let $(x, y, z) \in \mathcal{H}^3$. Define

$$
H(x, y) = \{ z \in \mathcal{H} \mid \langle z - y | x - y \rangle \le 0 \},\tag{4.8}
$$

 $C = H(x, y) \cap H(y, z)$, and, if $C \neq \emptyset$,

$$
Q(x, y, z) = \text{proj}_C x. \tag{4.9}
$$

Set $\chi = \langle x - y | y - z \rangle$, $\mu = ||x - y||^2$, $\nu = ||y - z||^2$ and $\rho = \mu \nu - \chi^2$. Then exactly one of the following holds:

- (i) $\rho = 0$ and $\chi < 0$, in which case $C = \emptyset$.
- (ii) $[\rho = 0 \text{ and } \chi \ge 0]$ or $\rho > 0$, in which case $C \neq \emptyset$ and

$$
Q(x, y, z) = \begin{cases} z, & \text{if } \rho = 0 \text{ and } \chi \ge 0, \\ x + (1 + \chi/\nu)(z - y), & \text{if } \rho > 0 \text{ and } \chi \nu \ge \rho, \\ y + (\nu/\rho)(\chi(x - y) + \mu(z - y)), & \text{if } \rho > 0 \text{ and } \chi \nu < \rho. \end{cases}
$$
(4.10)

Ĵ The essential components of the following theorem are found in the unpublished thesis of [Haugazeau](#page-136-13) [\(1968\)](#page-136-13) (see [Haugazeau](#page-136-12) [1967](#page-136-12) for a preliminary variant), where he considered the specific problem of projecting a point onto the intersection of finitely many sets using their individual projection operators cyclically.

Theorem 4.7. Let Z be a nonempty closed convex subset of H, let $(\lambda_n)_{n\in\mathbb{N}}$ be a sequence of relaxation parameters in [0, 1], and let $x_0 \in \mathcal{H}$. Iterate (see Figure [4.2\)](#page-35-0)

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nH_n \text{ is a closed half-space such that } Z \subset H_n \\
p_n = \text{proj}_{H_n} x_n \\
r_n = x_n + \lambda_n (p_n - x_n) \\
x_{n+1} = Q(x_0, x_n, r_n).\n\end{cases}
$$
\n(4.11)

Then the sequence $(x_n)_{n \in \mathbb{N}}$ is well defined and the following hold:

- (i) $(\forall n \in \mathbb{N})$ $Z \subset H(x_0, x_n) \cap H(x_n, r_n)$.
- (ii) $(\exists \ell \in [0, +\infty[) \|x_n - x_0\| \uparrow \ell \leq d_Z(x_0)).$
- (iii) $\sum_{n \in \mathbb{N}} ||x_{n+1} - x_n||^2 < +\infty$.
- (iv) $\sum_{n \in \mathbb{N}} \lambda_n^2 ||p_n - x_n||^2 < +\infty$.
- (v) Suppose that $\mathfrak{W}(x_n)_{n \in \mathbb{N}} \subset \mathbb{Z}$. Then $(x_n)_{n \in \mathbb{N}}$ converges strongly to proj_Z x_0 .

Proof. First, recall that the projector onto a nonempty closed convex subset D of H is characterized by [\(Bauschke and Combettes](#page-127-6) [2017,](#page-127-6) Theorem 3.16)

$$
(\forall x \in \mathcal{H})
$$
 $\text{proj}_D x \in D$ and $D \subset H(x, \text{proj}_D x)$. (4.12)

We also observe that (4.11) implies that

$$
(\forall n \in \mathbb{N}) \quad H(x_n, p_n)
$$

\n
$$
= \{ z \in \mathcal{H} \mid \langle z - p_n | x_n - r_n \rangle \le 0 \}
$$

\n
$$
= \{ z \in \mathcal{H} \mid \langle z - r_n | x_n - r_n \rangle \le \langle p_n - r_n | x_n - r_n \rangle \}
$$

\n
$$
= \{ z \in \mathcal{H} \mid \langle z - r_n | x_n - r_n \rangle \le -\lambda_n (1 - \lambda_n) ||x_n - p_n||^2 \}
$$

\n
$$
\subset H(x_n, r_n). \tag{4.13}
$$

[\(i\)](#page-33-1) Let $n \in \mathbb{N}$ be such that x_n exists. It follows from [\(4.11\)](#page-33-0) and [\(4.13\)](#page-34-0) that $Z \subset H_n$ = $H(x_n, p_n) \subset H(x_n, r_n)$. It is therefore enough to show that $Z \subset H(x_0, x_n)$. This inclusion certainly holds for $n = 0$ since $H(x_0, x_0) = H$. Furthermore, it follows from [\(4.12\)](#page-33-2) and [\(4.11\)](#page-33-0) that

$$
Z \subset H(x_0, x_n) \Rightarrow Z \subset H(x_0, x_n) \cap H(x_n, r_n)
$$

\n
$$
\Rightarrow Z \subset H(x_0, Q(x_0, x_n, r_n))
$$

\n
$$
\Leftrightarrow Z \subset H(x_0, x_{n+1}), \qquad (4.14)
$$

which establishes the assertion by induction. This also shows that $H(x_0, x_n) \cap$ $H(x_n, r_n) \neq \emptyset$ and hence that x_{n+1} is well defined.

[\(ii\)](#page-33-3)–[\(iii\)](#page-33-4) Let $n \in \mathbb{N}$. By construction, $x_{n+1} = \mathbb{Q}(x_0, x_n, r_n) \in H(x_0, x_n) \cap H(x_n, r_n)$. Consequently, since x_n is the projection of x_0 onto $H(x_0, x_n)$ and $x_{n+1} \in H(x_0, x_n)$, we have $||x_0 - x_n|| \le ||x_0 - x_{n+1}||$. On the other hand, since $\text{proj}_Z x_0 \in Z \subset H(x_0, x_n)$, we have $||x_0 - x_n|| \le ||x_0 - \text{proj}_Z x_0||$. It follows that $(||x_0 - x_k||)_{k \in \mathbb{N}}$ converges to some $\ell \in [0, ||x_0 - \text{proj}_Z x_0||]$, which establishes [\(ii\)](#page-33-3), and that

$$
\lim \|x_0 - x_k\| \le \|x_0 - \text{proj}_Z x_0\|.\tag{4.15}
$$

However, since $x_{n+1} \in H(x_0, x_n)$, we have

$$
||x_{n+1} - x_n||^2 \le ||x_{n+1} - x_n||^2 + 2\langle x_{n+1} - x_n | x_n - x_0 \rangle
$$

= $||x_0 - x_{n+1}||^2 - ||x_0 - x_n||^2$. (4.16)

Hence,

$$
\sum_{k=0}^{n} \|x_{k+1} - x_k\|^2 \le \|x_0 - x_{n+1}\|^2 \le \|x_0 - \text{proj}_Z x_0\|^2 \tag{4.17}
$$

and therefore

$$
\sum_{k \in \mathbb{N}} \|x_{k+1} - x_k\|^2 < +\infty. \tag{4.18}
$$

[\(iv\)](#page-33-5) For every $n \in \mathbb{N}$, we derive from the inclusion $x_{n+1} \in H(x_n, r_n)$ that

$$
||r_n - x_n||^2 \le ||x_{n+1} - r_n||^2 + ||x_n - r_n||^2
$$

\n
$$
\le ||x_{n+1} - r_n||^2 + 2\langle x_{n+1} - r_n | r_n - x_n \rangle + ||x_n - r_n||^2
$$

\n
$$
= ||x_{n+1} - x_n||^2.
$$
\n(4.19)

Figure 4.2. Iteration *n* of the Haugazeau-like algorithm [\(4.11\)](#page-33-0) with $\lambda_n = 1$.

Hence, by [\(iii\)](#page-33-4) and (4.11) ,

$$
\sum_{n \in \mathbb{N}} \lambda_n^2 ||p_n - x_n||^2 = \sum_{n \in \mathbb{N}} ||r_n - x_n||^2 < +\infty.
$$
 (4.20)

[\(v\)](#page-33-6) Let us note that [\(ii\)](#page-33-3) implies that $(x_n)_{n \in \mathbb{N}}$ is bounded. Now let $x \in \mathfrak{W}(x_n)_{n \in \mathbb{N}}$, say $x_{k_n} \rightarrow x$. Then, by weak lower semicontinuity of $\|\cdot\|$ [\(Bauschke and Combettes](#page-127-6) [2017,](#page-127-6) Lemma 2.42) and [\(ii\)](#page-33-3),

$$
||x_0 - x|| \le \underline{\lim} ||x_0 - x_{k_n}|| \le ||x_0 - \text{proj}_Z x_0|| = \inf_{z \in Z} ||x_0 - z||. \tag{4.21}
$$

Hence, since $x \in Z$, $x = \text{proj}_Z x_0$ is the only weak sequential cluster point of $(x_n)_{n \in \mathbb{N}}$ and it follows from Lemma [4.1](#page-30-4)[\(ii\)](#page-33-3) that $x_n \to \text{proj}_Z x_0$. In turn, (ii) yields

$$
||x_0 - \text{proj}_Z x_0|| \le \underline{\lim} ||x_0 - x_n|| = \lim ||x_0 - x_n|| \le ||x_0 - \text{proj}_Z x_0||. \tag{4.22}
$$

Thus, $x_0 - x_n \rightharpoonup x_0 - \text{proj}_Z x_0$ and $||x_0 - x_n|| \rightharpoonup ||x_0 - \text{proj}_Z x_0||$. We therefore derive from Lemma [4.1](#page-30-4)[\(iii\)](#page-30-8) that $x_0 - x_n \to x_0$ – proj_Z x_0 , i.e. $x_n \to \text{proj}_Z x_0$.

4.4. Graph-based cuts

We consider the problem of finding a zero of a maximally monotone operator $M: \mathcal{H} \to 2^{\mathcal{H}}$ decomposed as $M = W + C$, where $W: \mathcal{H} \to 2^{\mathcal{H}}$ is maximally monotone and $C: \mathcal{H} \to \mathcal{H}$ is cocoercive, using the geometric principles of Theorems [4.2](#page-30-6) and [4.7.](#page-33-7) To this end, we shall construct half-spaces by selecting points in the graph of W . Let us start with a weak convergence result.

Theorem 4.8. Let $\alpha \in [0, +\infty[$, let $W: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, let $C: \mathcal{H} \to \mathcal{H}$ be α -cocoercive and such that $Z = \text{zer}(W + C) \neq \emptyset$, let $x_0 \in \mathcal{H}$, and
let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in [0, 2]. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
(w_n, w_n^*) \in \text{gra } W, q_n \in \mathcal{H}
$$
\n
$$
t_n^* = w_n^* + Cq_n
$$
\n
$$
\delta_n = \langle x_n - w_n | t_n^* \rangle - ||w_n - q_n||^2 / (4\alpha)
$$
\n
$$
d_n = \begin{cases} \frac{\delta_n}{||t_n^*||^2} t_n^*, & \text{if } \delta_n > 0, \\ 0, & \text{otherwise} \end{cases}
$$
\n
$$
(4.23)
$$

J, Then the following hold:

- (i) $(x_n)_{n \in \mathbb{N}}$ is bounded.
- (ii) $\sum_{n \in \mathbb{N}} \lambda_n (2 - \lambda_n) ||d_n||^2 < +\infty$.
- (iii) Suppose that $w_n - x_n \rightharpoonup 0$, $w_n - q_n \rightharpoonup 0$ and $t_n^* \rightharpoonup 0$. Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z .

Proof. We first observe that [\(4.23\)](#page-36-0) is well defined since ($\forall n \in \mathbb{N}$) $\delta_n > 0 \Rightarrow$ $t_n^* \neq 0$. It follows from Example [2.5](#page-12-0) and Lemma [2.27](#page-17-0)[\(ii\)](#page-17-1) that

$$
W + C
$$
 is maximally monotone, (4.24)

and hence from [\(2.29\)](#page-8-0) that Z is a nonempty closed convex subset of H . Set

$$
(\forall n \in \mathbb{N}) \quad H_n = \left\{ z \in \mathcal{H} \mid \langle z - w_n \mid t_n^* \rangle \le \frac{\|w_n - q_n\|^2}{4\alpha} \right\} \tag{4.25}
$$

and let $z \in Z$. For every $n \in \mathbb{N}$, since $(z, -Cz) \in \text{gra } W$ and $(w_n, w_n^*) \in \text{gra } W$, it results from the monotonicity of W that $\langle w_n - z \mid w_n^* + Cz \rangle \ge 0$. Hence, since C is α -cocoercive,

$$
(\forall n \in \mathbb{N}) \quad \langle z - w_n | t_n^* \rangle
$$

\n
$$
= \langle z - w_n | w_n^* + Cq_n \rangle
$$

\n
$$
\leq \langle z - w_n | Cq_n - Cz \rangle
$$

\n
$$
= \langle q_n - w_n | Cq_n - Cz \rangle + \langle z - q_n | Cq_n - Cz \rangle
$$

\n
$$
\leq \langle q_n - w_n | Cq_n - Cz \rangle + \langle z - q_n | Cq_n - Cz \rangle
$$

\n
$$
\leq \langle q_n - w_n | Cq_n - Cz \rangle - \alpha ||Cq_n - Cz||^2
$$

\n
$$
= 2 \left\langle \frac{q_n - w_n}{\sqrt{4\alpha}} \right| \sqrt{\alpha} (Cq_n - Cz) - \left\| \sqrt{\alpha} (Cq_n - Cz) \right\|^2
$$

\n
$$
= \frac{\|w_n - q_n\|^2}{4\alpha} - \left\| \sqrt{\alpha} (Cq_n - Cz) + \frac{w_n - q_n}{\sqrt{4\alpha}} \right\|^2
$$

\n
$$
\leq \frac{\|w_n - q_n\|^2}{4\alpha}.
$$
\n(4.28)

This shows that $(\forall n \in \mathbb{N})$ Z $\subset H_n$. In addition, it results from [\(4.23\)](#page-36-0) and Example [2.1](#page-6-0) that

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n + \lambda_n (\operatorname{proj}_{H_n} x_n - x_n), \tag{4.29}
$$

which corresponds to the setting of Theorem [4.2.](#page-30-0)

[\(i\)](#page-36-1) This follows from Theorem [4.2](#page-30-0)[\(i\)](#page-30-1).

[\(ii\)](#page-36-2) This follows from Theorem [4.2](#page-30-0)[\(ii\)](#page-30-2).

[\(iii\)](#page-36-3) Let $x \in \mathfrak{W}(x_n)_{n \in \mathbb{N}}$, say $x_{k_n} \to x$. Then $w_{k_n} = x_{k_n} + (w_{k_n} - x_{k_n}) \to x$. On the other hand, since C is $1/\alpha$ -Lipschitzian,

$$
||w_n^* + Cw_n|| = ||t_n^* + Cw_n - Cq_n|| \le ||t_n^*|| + \frac{||w_n - q_n||}{\alpha} \to 0.
$$
 (4.30)

In addition, since $(w_n, w_n^*)_{n \in \mathbb{N}}$ is in gra W , $(w_n, w_n^* + Cw_n)_{n \in \mathbb{N}}$ is in gra $(W + C)$. It then follows from [\(4.24\)](#page-36-4) and Lemma [2.49](#page-22-0) that $x \in Z$. We conclude by invoking Theorem [4.2](#page-30-0)[\(iv\)](#page-31-0). \Box

We now turn to strong convergence.

Theorem 4.9. Let $\alpha \in [0, +\infty[$, let $W: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, let $C: \mathcal{H} \to \mathcal{H}$ be α -cocoercive and such that $Z = \text{zer}(W + C) \neq \emptyset$, let $x_0 \in \mathcal{H}$, and let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in [0, 1]. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n(w_n, w_n^*) \in \text{gra } W, q_n \in \mathcal{H} \\
t_n^* = w_n^* + Cq_n \\
\delta_n = \langle x_n - w_n | t_n^* \rangle - ||w_n - q_n||^2 / (4\alpha) \\
a_n = \begin{cases}\n\frac{\delta_n}{||t_n^*||^2} t_n^*, & \text{if } \delta_n > 0, \\
0, & \text{otherwise}\n\end{cases} \\
r_n = x_n - \lambda_n d_n \\
x_{n+1} = Q(x_0, x_n, r_n),\n\end{cases}
$$
\n(4.31)

where Q is defined in Lemma [4.6.](#page-33-0) Then the following hold:

- (i) $(x_n)_{n \in \mathbb{N}}$ is bounded.
- (ii) $\sum_{n \in \mathbb{N}} ||x_{n+1} - x_n||^2 < +\infty$.
- (iii) $\sum_{n \in \mathbb{N}} \lambda_n^2 ||d_n||^2 < +\infty$.
- (iv) Suppose that $w_n - x_n \rightharpoonup 0$, $w_n - q_n \rightharpoonup 0$ and $t_n^* \rightharpoonup 0$. Then $(x_n)_{n \in \mathbb{N}}$ converges strongly to $proj_Z x_0$.

Proof. Define $(H_n)_{n \in \mathbb{N}}$ as in [\(4.25\)](#page-36-5) and note that [\(4.28\)](#page-36-6) yields $Z \subset \bigcap_{n \in \mathbb{N}} H_n$. Furthermore, we derive from [\(4.31\)](#page-37-0) and Example [2.1](#page-6-0) that ($\forall n \in \mathbb{N}$) $r_n = x_n +$ λ_n (proj_{H_n} $x_n - x_n$). This places us in the setting of Theorem [4.7.](#page-33-1)

[\(i\)](#page-37-1) This follows from Theorem [4.7](#page-33-1)[\(ii\)](#page-33-2).

- [\(ii\)](#page-37-2) See Theorem [4.7](#page-33-1)[\(iii\)](#page-33-3).
- [\(iii\)](#page-37-3) This follows from Theorem [4.7](#page-33-1)[\(iv\)](#page-33-4).

[\(iv\)](#page-37-4) As in the proof of Theorem [4.8](#page-35-0)[\(iii\)](#page-36-3), $\mathfrak{W}(x_n)_{n \in \mathbb{N}} \subset \mathbb{Z}$. The claim follows from Theorem $4.7(v)$ $4.7(v)$. П

In the absence of the cocoercive operator C, we can choose $(q_n)_{n \in \mathbb{N}} = (w_n)_{n \in \mathbb{N}}$ in [\(4.23\)](#page-36-0) and [\(4.31\)](#page-37-0), and Theorems [4.8](#page-35-0) and [4.9](#page-37-5) simplify as follows.

Proposition 4.10. Let $M: \mathcal{H} \to 2^{\mathcal{H}}$ be a maximally monotone operator such that $Z = \text{zer } M \neq \emptyset$, let $x_0 \in \mathcal{H}$, and let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $[0, 2]$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n(m_n, m_n^*) \in \text{gra } M \\
\frac{\langle x_n - m_n | m_n^* \rangle}{\|m_n^*\|^2} m_n^*, & \text{if } \langle x_n - m_n | m_n^* \rangle > 0, \\
0, & \text{otherwise}\n\end{cases}
$$
\n(4.32)

J Then the following hold:

- (i) $\sum_{n \in \mathbb{N}} \lambda_n (2 \lambda_n) ||d_n||^2 < +\infty$.
- (ii) Suppose that $m_n x_n \rightharpoonup 0$ and $m_n^* \rightharpoonup 0$. Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z.

Proposition 4.11. Let $M: \mathcal{H} \to 2^{\mathcal{H}}$ be a maximally monotone operator such that $Z = \text{zer } M \neq \emptyset$, let $x_0 \in \mathcal{H}$, and let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in [0, 1]. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n(m_n, m_n^*) \in \text{gra } M \\
\frac{\langle x_n - m_n | m_n^* \rangle}{\|m_n^*\|^2} m_n^*, & \text{if } \langle x_n - m_n | m_n^* \rangle > 0, \\
0, & \text{otherwise}\n\end{cases}
$$
\n
$$
\begin{cases}\n\sum_{n=1}^{\infty} \frac{1}{n} \sum_{n=1}^{\infty} \frac{1}{n} m_n^*, & \text{if } \langle x_n - m_n | m_n^* \rangle > 0, \\
\sum_{n=1}^{\infty} \frac{1}{n} \sum_{n=1}^{\infty} \frac{1}{n}
$$

where Q is defined in Lemma [4.6.](#page-33-0) Then the following hold:

- (i) $\sum_{n \in \mathbb{N}} \lambda_n^2 ||d_n||^2 < +\infty$.
- (ii) Suppose that $m_n x_n \rightharpoonup 0$ and $m_n^* \rightharpoonup 0$. Then $(x_n)_{n \in \mathbb{N}}$ converges strongly to $proj_Z x_0$.

4.5. Warped resolvent cuts

Algorithms [\(4.23\)](#page-36-0) and [\(4.31\)](#page-37-0) are conceptual in the sense that they do not provide an explicit mechanism to find points in the graph of W . In this section, we propose implementable versions that pick points in gra W using the warped resolvents of Lemma [2.42.](#page-21-0)

Theorem 4.12. Let $\alpha \in]0, +\infty[$, let $W: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, let $C: \mathcal{H} \to \mathcal{H}$ be α -cocoercive and such that $Z = \text{zer}(W + C) \neq \emptyset$, let $x_0 \in \mathcal{H}$, and let $(\lambda_n)_{n\in\mathbb{N}}$ be a sequence in $]0,2[$. Further, for every $n \in \mathbb{N}$, let $U_n: \mathcal{H} \to \mathcal{H}$ be an operator such that ran $U_n \subset \text{ran}(U_n + W + C)$ and $U_n + W + C$ is injective. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nw_n = J_{W+C}^{U_n} x_n \\
w_n^* = U_n x_n - U_n w_n - C w_n \\
q_n \in \mathcal{H} \\
t_n^* = w_n^* + C q_n \\
\delta_n = \langle x_n - w_n | t_n^* \rangle - ||w_n - q_n||^2 / (4\alpha) \\
d_n = \begin{cases}\n\frac{\delta_n}{||t_n^*||^2} t_n^*, & \text{if } \delta_n > 0, \\
0, & \text{otherwise}\n\end{cases} \\
x_{n+1} = x_n - \lambda_n d_n.\n\tag{4.34}
$$

Then the following hold:

- (i) $\sum_{n \in \mathbb{N}} \lambda_n (2 - \lambda_n) ||d_n||^2 < +\infty$.
- (ii) Suppose that one of the following is satisfied:
	- (a) $\sum_{n \in \mathbb{N}} \lambda_n (2 \lambda_n) = +\infty$ and $(\Vert d_n \Vert)_{n \in \mathbb{N}}$ converges,
	- (b) $\inf_{n \in \mathbb{N}} \lambda_n > 0$ and $\sup \lambda_n < 2$,

together with one of the following:

- (c) $w_n - x_n \to 0$, $U_n w_n - U_n x_n \to 0$ and $w_n - q_n \to 0$,
- (d) $q_n - x_n \to 0$ and there exist $\beta_1 \in [1/(4\alpha), +\infty[$ and $\beta_2 \in [0, +\infty[$ such that the kernels $(U_n)_{n \in \mathbb{N}}$ are β_1 -strongly monotone and β_2 -Lipschitzian.

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z.

Proof. Lemma [2.42\(](#page-21-0)[i\)](#page-21-1) indicates that [\(4.34\)](#page-39-0) is governed by the scenario of Theorem [4.8.](#page-35-0)

[\(i\)](#page-39-1) See Theorem [4.8](#page-35-0)[\(ii\)](#page-36-2).

[\(ii\)](#page-39-2) A consequence of [\(i\)](#page-39-1) under [\(iia\)](#page-39-3) or [\(iib\)](#page-39-4) is that

$$
||d_n|| \to 0. \tag{4.35}
$$

Indeed, the claim is clear under [\(iib\)](#page-39-4), whereas under [\(iia\)](#page-39-3) we have $\lim ||d_n|| = 0$ and therefore $\lim ||d_n|| = 0$. Next, let us assume that [\(iic\)](#page-39-5) holds. Then it follows from [\(4.34\)](#page-39-0) and [\(2.32\)](#page-8-1) that

$$
(\forall n \in \mathbb{N}) \quad ||t_n^*|| = ||U_n w_n - U_n x_n + C w_n - C q_n||
$$

\n
$$
\le ||U_n w_n - U_n x_n|| + ||C w_n - C q_n|| \tag{4.36}
$$

THE GEOMETRY OF MONOTONE OPERATOR SPLITTING METHODS 527

$$
\leq ||U_n w_n - U_n x_n|| + \frac{||w_n - q_n||}{\alpha}
$$

\n
$$
\to 0.
$$
 (4.37)

In view of Theorem [4.8](#page-35-0)[\(iii\)](#page-36-3), the claim is established. It remains to show that [\(iid\)](#page-39-6)⇒[\(iic\)](#page-39-5). Because the operators $(U_n + W + C)_{n \in \mathbb{N}}$ are β_1 -strongly monotone, the operators $(U_n + W + C)^{-1}_{n \in \mathbb{N}}$ are β_1 -cocoercive, hence $1/\beta_1$ -Lipschitzian. Consequently, since the operators $(U_n)_{n \in \mathbb{N}}$ are β_2 -Lipschitzian, the operators $(J_{W}^{U_{n}})$ $\binom{U_n}{W+C}_{n\in\mathbb{N}}$ are β_2/β_1 -Lipschitzian. Now let $z \in Z$. Then we derive from [\(4.34\)](#page-39-0) and Lemma [2.42\(](#page-21-0)[ii\)](#page-21-2) that

$$
(\forall n \in \mathbb{N}) \ \|w_n - z\| = \|J_{W+C}^{U_n} x_n - J_{W+C}^{U_n} z\| \le \frac{\beta_2}{\beta_1} \|x_n - z\|.
$$
 (4.38)

Appealing to Theorem [4.8\(](#page-35-0)[i\)](#page-36-1), we infer that $(w_n)_{n \in \mathbb{N}}$ is bounded. Thus, since $q_n - x_n \to 0$ and C is $1/\alpha$ -Lipschitzian, the sequences

 $(\|w_n - x_n\|)_{n \in \mathbb{N}}$, $(\|w_n - q_n\|)_{n \in \mathbb{N}}$ and $(\|Cw_n - Cq_n\|)_{n \in \mathbb{N}}$ are bounded. (4.39) However, [\(4.36\)](#page-39-7) entails that

$$
(\forall n \in \mathbb{N}) \quad ||t_n^*|| \le \beta_2 ||w_n - x_n|| + \frac{||w_n - q_n||}{\alpha}, \tag{4.40}
$$

which verifies that $(||t_n^*||)_{n \in \mathbb{N}}$ is bounded. In turn, [\(4.34\)](#page-39-0) and [\(4.35\)](#page-39-8) imply that

$$
\overline{\lim} \delta_n \le \lim \|t_n^*\| \|d_n\| = 0. \tag{4.41}
$$

Moreover, for every $n \in \mathbb{N}$, [\(4.34\)](#page-39-0) yields

$$
\delta_n = \langle w_n - x_n | U_n w_n - U_n x_n \rangle + \langle w_n - x_n | C w_n - C q_n \rangle - \frac{\|w_n - q_n\|^2}{4\alpha}
$$

\n
$$
\geq \beta_1 \|w_n - x_n\|^2 + \langle w_n - q_n | C w_n - C q_n \rangle + \langle q_n - x_n | C w_n - C q_n \rangle
$$

\n
$$
- \frac{\|w_n - q_n\|^2}{4\alpha}
$$

\n
$$
\geq \beta_1 (\|w_n - q_n\|^2 + 2\langle w_n - q_n | q_n - x_n \rangle + \|q_n - x_n\|^2)
$$

\n
$$
+ \alpha \|C w_n - C q_n\|^2 + \langle q_n - x_n | C w_n - C q_n \rangle - \frac{\|w_n - q_n\|^2}{4\alpha}
$$

\n
$$
\geq \left(\beta_1 - \frac{1}{4\alpha}\right) \|w_n - q_n\|^2 + \beta_1 (2\langle w_n - q_n | q_n - x_n \rangle + \|q_n - x_n\|^2)
$$

\n
$$
+ \langle q_n - x_n | C w_n - C q_n \rangle
$$

\n
$$
\geq \left(\beta_1 - \frac{1}{4\alpha}\right) \|w_n - q_n\|^2
$$

\n
$$
+ \|q_n - x_n\| (\beta_1 \|q_n - x_n\| - 2\beta_1 \|w_n - q_n\| + \|C w_n - C q_n\|).
$$
 (4.42)

Therefore, since $||q_n - x_n|| \to 0$, it follows from [\(4.39\)](#page-40-0) and [\(4.41\)](#page-40-1) that $w_n - q_n \to 0$

and hence that $w_n - x_n \to 0$. Since

$$
||U_n w_n - U_n x_n|| \le \beta_2 ||w_n - x_n|| \le \beta_2 (||w_n - q_n|| + ||q_n - x_n||) \to 0, \quad (4.43)
$$

 \Box

the proof is complete.

Remark 4.13. In the special case when $C = 0$, $(q_n)_{n \in \mathbb{N}} = (w_n)_{n \in \mathbb{N}}$, and conditions [\(iib\)](#page-39-4) and [\(iic\)](#page-39-5) are satisfied, Theorem [4.12](#page-39-9)[\(ii\)](#page-39-2) is closely related to Theorem 4.2(ii) of [Bùi and Combettes](#page-130-0) [\(2020](#page-130-0)*b*).

We conclude this section with the strongly convergent best approximation companion algorithm resulting from Theorem [4.9.](#page-37-5)

Theorem 4.14. Let $\alpha \in]0, +\infty[$, let $W: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, let $C: \mathcal{H} \to \mathcal{H}$ be α -cocoercive and such that $Z = \text{zer}(W + C) \neq \emptyset$, let $x_0 \in \mathcal{H}$, and let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in [0, 1]. Further, for every $n \in \mathbb{N}$, let $U_n: \mathcal{H} \to \mathcal{H}$ be an operator such that ran $U_n \subset \text{ran}(U_n + W + C)$ and $U_n + W + C$ is injective. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{aligned}\nw_n &= J_{W+C}^{U_n} x_n \\

\n(4.44)

where Q is defined in Lemma [4.6.](#page-33-0) Then the following hold:

- (i) $\sum_{n \in \mathbb{N}} \lambda_n^2 ||d_n||^2 < +\infty$.
- (ii) Suppose that one of the following is satisfied:
	- (a) $\sum_{n \in \mathbb{N}} \lambda_n^2 = +\infty$ and $(\Vert d_n \Vert)_{n \in \mathbb{N}}$ converges,
	- (b) $\inf_{n \in \mathbb{N}} \lambda_n > 0$,

together with one of the following:

- (c) $w_n - x_n \to 0$, $U_n w_n - U_n x_n \to 0$ and $w_n - q_n \to 0$,
- (d) $q_n - x_n \to 0$ and there exist $\beta_1 \in [1/(4\alpha), +\infty[$ and $\beta_2 \in [0, +\infty[$ such that the kernels $(U_n)_{n \in \mathbb{N}}$ are β_1 -strongly monotone and β_2 -Lipschitzian.

Then $(x_n)_{n \in \mathbb{N}}$ converges strongly to proj_Z x_0 .

Proof. In view of Lemma [2.42\(](#page-21-0)[i\)](#page-21-1), [\(4.44\)](#page-41-0) is an instance of [\(4.31\)](#page-37-0) and we shall therefore employ Theorem [4.9.](#page-37-5)

[\(i\)](#page-41-1) See Theorem [4.9](#page-37-5)[\(iii\)](#page-37-3).

[\(ii\)](#page-41-2) It follows from [\(i\)](#page-41-1) and [\(4.44\)](#page-41-0) that $d_n \to 0$. Indeed, this is evident under [\(iib\)](#page-41-3), whereas under [\(iia\)](#page-39-3) we have $\lim ||d_n|| = 0$ and therefore $\lim ||d_n|| = 0$. Let us now assume that [\(iic\)](#page-41-4) holds. Then [\(4.37\)](#page-40-2) is satisfied and we obtain the assertion by invoking Theorem [4.9](#page-37-5)[\(iv\)](#page-37-4). Finally, to show that [\(iid\)](#page-41-5)⇒[\(iic\)](#page-41-4), we remark that Theorem [4.9](#page-37-5)[\(i\)](#page-37-1) asserts that $(x_n)_{n \in \mathbb{N}}$ is bounded. Hence, we follow the same pattern as in the proof of Theorem [4.12](#page-39-9)[\(iid\)](#page-39-6) to conclude. \Box

5. The proximal point algorithm

5.1. Preview

The proximal point algorithm is an implicit method to construct a zero of a maximally monotone operator which goes back to a quadratic programming method proposed in [Bellman, Kalaba and Lockett](#page-128-0) [\(1966,](#page-128-0) Section 5.8). In the nonlinear case, it first appeared in the work of [Lieutaud](#page-138-0) [\(1969](#page-138-0)*a*) (this fact seems to have been overlooked in the literature: see Remark [6.1\)](#page-58-0), then in [Martinet](#page-139-0) [\(1970,](#page-139-0) [1972\)](#page-139-1) for subdifferentials and [Rockafellar](#page-141-0) $(1976b)$ $(1976b)$ for the general case. Iteration *n* of the unrelaxed form of the algorithm can be interpreted as a backward Euler discretization of the Cauchy problem [\(Aubin and Cellina](#page-127-0) [1984,](#page-127-0) Section 3.2) (see Example [2.18\)](#page-14-0)

$$
\begin{cases} x(0) = x_0, \\ -x'(t) \in Mx(t), \text{ for a.e. } t \in]0, +\infty[, \end{cases}
$$
 (5.1)

with time step $\gamma_n \in]0, +\infty[$, that is,

$$
\frac{x_n - x_{n+1}}{\gamma_n} \in Mx_{n+1} \tag{5.2}
$$

or, equivalently, $x_{n+1} = J_{\gamma_n} M x_n$.

5.2. Fejérian algorithm

The following theorem, which brings together results from [Brézis and Lions\(1978\)](#page-129-0), [Eckstein and Bertsekas](#page-134-0) [\(1992\)](#page-134-0), [Gabay](#page-135-0) [\(1983\)](#page-135-0), [Gol'shtein and Tret'yakov](#page-136-0) [\(1979\)](#page-136-0), [Lemaire](#page-138-1) [\(1989\)](#page-138-1), [Martinet](#page-139-0) [\(1970,](#page-139-0) [1972\)](#page-139-1) and [Rockafellar](#page-141-0) [\(1976](#page-141-0)*b*), will be derived from Theorem [4.12.](#page-39-9)

Theorem 5.1. Let $M: \mathcal{H} \to 2^{\mathcal{H}}$ be a maximally monotone operator such that $Z = \text{zer } M \neq \emptyset$, let $x_0 \in \mathcal{H}$, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $[0, 2]$, and let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $]0, +\infty[$. Iterate

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n + \lambda_n (J_{\gamma_n M} x_n - x_n), \tag{5.3}
$$

and suppose that one of the following holds:

(i)
$$
\sum_{n \in \mathbb{N}} \lambda_n (2 - \lambda_n) = +\infty
$$
 and $(\forall n \in \mathbb{N}) \gamma_n = 1$.

- (ii) $\sum_{n \in \mathbb{N}} \gamma_n^2 = +\infty$ and $(\forall n \in \mathbb{N}) \lambda_n = 1$.
- (iii) $\inf_{n \in \mathbb{N}} \lambda_n > 0$, $\sup_{n \in \mathbb{N}} \lambda_n < 2$ and $\inf_{n \in \mathbb{N}} \gamma_n > 0$.

Then $||J_{\gamma_n} M x_n - x_n|| / \gamma_n \to 0$ and $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z.

Proof. Let us apply Theorem [4.12](#page-39-9) with

$$
C = 0 \quad \text{and} \quad (\forall n \in \mathbb{N}) \quad U_n = \gamma_n^{-1} \text{Id} \quad \text{and} \quad q_n = w_n. \tag{5.4}
$$

We derive from (2.19) that the variables of the iterations (4.34) satisfy

$$
(\forall n \in \mathbb{N}) \quad t_n^* = \frac{x_n - w_n}{\gamma_n}, \quad \delta_n = \gamma_n ||t_n^*||^2 \quad \text{and} \quad d_n = x_n - w_n. \tag{5.5}
$$

Thus, the sequence $(x_n)_{n \in \mathbb{N}}$ produced by [\(5.3\)](#page-42-0) coincides with that of [\(4.34\)](#page-39-0). In turn, Theorem [4.12](#page-39-9)[\(i\)](#page-39-1) yields

$$
\sum_{n \in \mathbb{N}} \lambda_n (2 - \lambda_n) ||d_n||^2 < +\infty. \tag{5.6}
$$

We now show that one of conditions [\(iia\)](#page-39-3)–[\(iib\)](#page-39-4) and one of conditions [\(iic\)](#page-39-5)–[\(iid\)](#page-39-6) of Theorem $4.12(ii)$ $4.12(ii)$ are fulfilled in each scenario. We also recall from (4.35) that [\(iia\)](#page-39-3) and [\(iib\)](#page-39-4) in Theorem [4.12](#page-39-9) each imply that

$$
d_n \to 0. \tag{5.7}
$$

[\(i\)](#page-42-1) Let us check that conditions [\(iia\)](#page-39-3) and [\(iid\)](#page-39-6) are fulfilled. For [\(iia\)](#page-39-3), it is enough to show that $(\Vert d_n \Vert)_{n \in \mathbb{N}}$ decreases. To this end, set $T = 2J_M - \text{Id}$. Then Lemma [2.34](#page-20-0)[\(iii\)](#page-20-1) and [\(2.33\)](#page-8-2) assert that T is nonexpansive. Therefore, [\(5.5\)](#page-43-0) yields

$$
(\forall n \in \mathbb{N}) \quad 2||d_{n+1}|| = ||Tx_{n+1} - x_{n+1}||
$$

\n
$$
= ||Tx_{n+1} - Tx_n + (1 - \lambda_n/2)(Tx_n - x_n)||
$$

\n
$$
\le ||x_{n+1} - x_n|| + (1 - \lambda_n/2)||Tx_n - x_n||
$$

\n
$$
= (\lambda_n/2)||Tx_n - x_n|| + (1 - \lambda_n/2)||Tx_n - x_n||
$$

\n
$$
= 2||d_n||, \qquad (5.8)
$$

as desired. For [\(iid\)](#page-39-6), note that [\(5.7\)](#page-43-1) and [\(5.5\)](#page-43-0) imply that $q_n - x_n = w_n - x_n =$ $-d_n \to 0$. In addition, it is clear from [\(5.4\)](#page-43-2) that $(U_n)_{n \in \mathbb{N}}$ satisfies the required conditions with $\beta_1 = \beta_2 = 1$.

[\(ii\)](#page-43-3) Condition [\(iib\)](#page-39-4) holds. To show that [\(iic\)](#page-39-5) holds as well, we first infer from [\(5.5\)](#page-43-0) and [\(5.6\)](#page-43-4) that $\sum_{n \in \mathbb{N}} \gamma_n^2 ||t_n^*||^2 < +\infty$ and hence that $w_n - x_n = -\gamma_n t_n^* \to 0$. Furthermore, since $\sum_{n \in \mathbb{N}} \gamma_n^2 = +\infty$, $\lim_{n \to \infty} ||t_n|| = 0$. On the other hand, $(\forall n \in \mathbb{N})$ $t_n^* = \gamma_n^{-1}(x_n - w_n) = \gamma_n^{-1}(x_n - x_{n+1})$. Hence, using [\(2.18\)](#page-7-1), the monotonicity of M and the Cauchy–Schwarz inequality, we obtain

$$
(\forall n \in \mathbb{N}) \quad 0 \le \langle w_n - w_{n+1} \mid t_n^* - t_{n+1}^* \rangle / \gamma_{n+1}
$$

= $\langle x_{n+1} - x_{n+2} \mid t_n^* - t_{n+1}^* \rangle / \gamma_{n+1}$
= $\langle t_{n+1}^* \mid t_n^* - t_{n+1}^* \rangle$

$$
= \langle t_{n+1}^* \mid t_n^* \rangle - ||t_{n+1}^*||^2
$$

\n
$$
\leq ||t_{n+1}^*||(||t_n^*|| - ||t_{n+1}^*||),
$$
\n(5.9)

which shows that $(||t_n^*||)_{n \in \mathbb{N}}$ decreases. Altogether, $U_n x_n - U_n w_n = t_n^* \to 0$.

[\(iii\)](#page-43-5) Condition [\(iib\)](#page-39-4) is assumed. Let us check [\(iic\)](#page-39-5). Since [\(5.5\)](#page-43-0) and [\(5.6\)](#page-43-4) yield $\sum_{n \in \mathbb{N}} \gamma_n^2 ||t_n^*||^2 < +\infty$, we have $x_n - w_n = \gamma_n t_n^* \to 0$. Finally, since $\inf_{n \in \mathbb{N}} \gamma_n > 0$, $U_n x_n - U_n w_n = t_n^* \to 0.$

We conclude the proof by noting that in all three cases above $||J_{\gamma_n}U_{\gamma_n}-X_n||/\gamma_n =$ $||t_n^*|| \to 0.$

Remark 5.2. Let $f \in \Gamma_0(\mathcal{H})$ and suppose that $M = \partial f$ in Theorem [5.1.](#page-42-2) Then, as seen in Example [2.12,](#page-13-0) M is maximally monotone and $Z = \text{Argmin } f$. In this case, the condition on $(\gamma_n)_{n \in \mathbb{N}}$ in Theorem [5.1\(](#page-42-2)[ii\)](#page-43-3) can be improved to $\sum_{n \in \mathbb{N}} \gamma_n = +\infty$ [\(Brézis and Lions](#page-129-0) [1978,](#page-129-0) Théorème 9).

5.3. Haugazeau-like algorithm

We employ Theorem [4.14](#page-41-6) to obtain a strongly convergent variant of the proximal point algorithm; see [Bauschke and Combettes](#page-127-1) [\(2001\)](#page-127-1) and [Solodov and Svaiter](#page-142-0) [\(2000\)](#page-142-0) for related results. Examples of proximal point iterations that fail to converge strongly are constructed in [Bauschke, Matoušková and Reich](#page-128-1) [\(2004\)](#page-128-1), [Combettes](#page-132-0) [\(2018\)](#page-132-0) and [Güler](#page-136-1) [\(1991\)](#page-136-1).

Theorem 5.3. Let $M: \mathcal{H} \to 2^{\mathcal{H}}$ be a maximally monotone operator such that $Z =$ zer $M \neq \emptyset$, let $x_0 \in \mathcal{H}$, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in [0, 1] such that inf $n \in \mathbb{N}$ $\lambda_n > 0$, and let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $]0, +\infty[$ such that $\inf_{n \in \mathbb{N}} \gamma_n > 0$. Iterate

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = \mathbf{Q}(x_0, x_n, x_n + \lambda_n (J_{\gamma_n M} x_n - x_n)), \tag{5.10}
$$

where Q is defined in Lemma [4.6.](#page-33-0) Then $(x_n)_{n \in \mathbb{N}}$ converges strongly to proj_Z x_0 .

Proof. In Theorem [4.14,](#page-41-6) set $C = 0$ and $(\forall n \in \mathbb{N})$ $U_n = \gamma_n^{-1}$ Id and $q_n = w_n$. Then [\(5.5\)](#page-43-0) holds and the sequence $(x_n)_{n \in \mathbb{N}}$ produced by [\(5.10\)](#page-44-0) coincides with that of [\(4.44\)](#page-41-0). In turn, Theorem [4.14](#page-41-6)[\(i\)](#page-41-1) yields $\sum_{n \in \mathbb{N}} \lambda_n^2 ||d_n||^2 < +\infty$. Therefore, $x_n - w_n = d_n \to 0$ and $U_n x_n - U_n w_n = \gamma_n^{-1} d_n \to 0$. This confirms that condition [\(iic\)](#page-41-4) in Theorem [4.14](#page-41-6)[\(ii\)](#page-41-2) is fulfilled. Since condition [\(iib\)](#page-41-3) holds by assumption, the \Box proof is complete.

5.4. Special cases and variants

As mentioned in Section [1,](#page-1-0) direct implementations of the proximal point algorithm are limited due to the potential difficulty of evaluating the resolvents in [\(5.3\)](#page-42-0) and [\(5.10\)](#page-44-0). As we shall see in this section, the proximal point framework can nonetheless be an effective device to establish indirectly the convergence of algorithms that can be identified, possibly in a different space, as an instance of [\(5.3\)](#page-42-0). Early examples in the context of inequality-constrained minimization problems are found in [Rockafellar](#page-141-1) [\(1976](#page-141-1)*a*), where a dual application of an approximate proximal point algorithm was shown to yield a method of multipliers (also called the augmented Lagrangian method) that extends some classical ones from [Hestenes](#page-137-0) [\(1969\)](#page-137-0) and [Powell](#page-141-2) [\(1969\)](#page-141-2); see also [Rockafellar](#page-141-3) [\(1973\)](#page-141-3). A primal–dual quadratically perturbed variant of this algorithm, known as the proximal method of multipliers, was also introduced in [Rockafellar](#page-141-1) [\(1976](#page-141-1)*a*) as an application of an approximate proximal point algorithm to find saddle points of the Lagrangian; see also [Rockafellar](#page-142-1) [\(2024\)](#page-142-1), [Shefi and Teboulle](#page-142-2) [\(2014\)](#page-142-2) and their bibliographies for recent work along these lines. The applications described below reduce to implementations of the proximal point algorithm that feature full operator splitting when several linear and nonlinear operators are present in the original problem.

5.4.1. The Euler method

We derive from the proximal point algorithm a (forward) Euler method to find a zero of a cocoercive operator.

Proposition 5.4. Let $\alpha \in [0, +\infty[$ and let $B: \mathcal{H} \to \mathcal{H}$ be α -cocoercive, with zer $B \neq \emptyset$. Let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $]0, 2\alpha[$ such that $\sum_{n \in \mathbb{N}} \gamma_n(2\alpha - \gamma_n) = +\infty$ and let $x_0 \in \mathcal{H}$. Iterate

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n - \gamma_n B x_n. \tag{5.11}
$$

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in zer *B*.

Proof. Set $M = (\text{Id} - \alpha B)^{-1} - \text{Id}$. Since αB is firmly nonexpansive with domain H , Id – αB is likewise and Lemma [2.34\(](#page-20-0)[iii\)](#page-20-1) asserts that M is maximally monotone. On the other hand, zer $M =$ zer B, $J_M =$ Id $-\alpha B$, and hence [\(5.11\)](#page-45-0) becomes

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n + \lambda_n (J_M x_n - x_n), \quad \text{where } \lambda_n = \gamma_n / \alpha \in]0, 2[.
$$
 (5.12)

Thus, since $\sum_{n \in \mathbb{N}} \lambda_n (2 - \lambda_n) = +\infty$, the claim follows from Theorem [5.1\(](#page-42-2)[i\)](#page-42-1). \Box

Remark 5.5. As just shown, the Euler method [\(5.11\)](#page-45-0) is an instance of the proximal point algorithm [\(5.3\)](#page-42-0). Conversely, we can interpret the proximal point iterations in the format

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n + \lambda_n (J_M x_n - x_n), \quad \text{where } \lambda_n \in [0, 2[, \tag{5.13}
$$

as an instance of [\(5.11\)](#page-45-0). Indeed, let $M: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone and set $B = {}^{1}M$ and ($\forall n \in \mathbb{N}$) $\gamma_n = \lambda_n$. Then, as seen in Example [2.7,](#page-12-1) zer $M =$ zer B and B is 1-cocoercive, while (2.21) implies that (5.13) reduces to (5.11) .

The following example is about the gradient method; see [Cauchy](#page-131-0) [\(1847\)](#page-131-0) and [Curry](#page-133-0) [\(1944\)](#page-133-0) for the premises of this algorithm.

Example 5.6. Let $\alpha \in [0, +\infty[$ and let $g: \mathcal{H} \to \mathbb{R}$ be convex, differentiable, and such that ∇g is $1/\alpha$ -Lipschitzian, with Argmin $g \neq \emptyset$. Let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $]0, 2\alpha[$ such that $\sum_{n \in \mathbb{N}} \gamma_n(2\alpha - \gamma_n) = +\infty$ and let $x_0 \in \mathcal{H}$. Iterate

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n - \gamma_n \nabla g(x_n). \tag{5.14}
$$

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Argmin g.

Proof. Combine Lemma [2.2](#page-9-0) and Proposition [5.4.](#page-45-2)

As noted in [Bauschke, Combettes and Reich](#page-128-2) [\(2005,](#page-128-2) Remark 4.8(ii)) in the context of Example [5.6,](#page-45-3) the convergence in Proposition [5.4](#page-45-2) can fail to be strong. The next result, which guarantees strong convergence, is obtained by defining M and $(\lambda_n)_{n \in \mathbb{N}}$ as in the proof of Proposition [5.4](#page-45-2) and using Theorem [5.3.](#page-44-1)

Proposition 5.7. Let $\alpha \in [0, +\infty[$ and let $B: \mathcal{H} \to \mathcal{H}$ be α -cocoercive, with zer $B \neq \emptyset$. Let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $]0, \alpha]$ such that $\inf_{n \in \mathbb{N}} \gamma_n > 0$ and let $x_0 \in \mathcal{H}$. Iterate

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = \mathsf{Q}(x_0, x_n, x_n - \gamma_n B x_n), \tag{5.15}
$$

where Q is defined in Lemma [4.6.](#page-33-0) Then $(x_n)_{n \in \mathbb{N}}$ converges strongly to proj_{zer B} x_0 .

5.4.2. Fixed point problem

We address the basic problem of constructing a fixed point of a nonexpansive operator $T: \mathcal{H} \to \mathcal{H}$. The following result is derived as an instance of the proximal point algorithm of Theorem [5.1](#page-42-2) via the embedding of Example [3.16.](#page-27-0)

Proposition 5.8. Let $\alpha \in [0, 1]$ and let $T: \mathcal{H} \to \mathcal{H}$ be α -*averaged*. Suppose that Fix $T \neq \emptyset$, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $]0, 1/\alpha[$ such that $\sum_{n \in \mathbb{N}} \lambda_n (1 - \alpha \lambda_n) = +\infty$, and let $x_0 \in \mathcal{H}$. Iterate

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n + \lambda_n (Tx_n - x_n). \tag{5.16}
$$

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Fix T.

Proof. We use the embedding of Example [3.16.](#page-27-0) Define M as in [\(3.26\)](#page-27-1) and note that $J_{\mathcal{M}} = \text{Id} + (2\alpha)^{-1}(T - \text{Id})$. We therefore rewrite [\(5.16\)](#page-46-0) as

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n + \mu_n (J_{\mathcal{M}} x_n - x_n), \quad \text{where } \mu_n = 2\alpha \lambda_n \in [0, 2[. \quad (5.17)
$$

Then $\sum_{n \in \mathbb{N}} \mu_n(2 - \mu_n) = +\infty$ and, appealing to Theorem [5.1\(](#page-42-2)[i\)](#page-42-1), we conclude that $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in zer $\mathcal{M} = \text{Fix } T$. \Box

In the case when $\alpha = 1$, Proposition [5.8](#page-46-1) is due to [Groetsch](#page-136-2) [\(1972\)](#page-136-2) and [\(5.16\)](#page-46-0) is known as the *Krasnosel'ski˘ı–Mann iteration*, owing to its connection with iterative schemes proposed in Krasnosel'skiï [\(1955\)](#page-137-1) and [Mann](#page-139-2) [\(1953\)](#page-139-2), and it is a pillar of nonlinear numerical functional analysis [\(Bauschke and Combettes](#page-127-2) [2017,](#page-127-2) [Cegielski](#page-131-1) [2012,](#page-131-1) [Dong](#page-134-1) *et al.* [2022\)](#page-134-1). Here is a strongly convergent variant derived from Theorem [5.3;](#page-44-1) see [Genel and Lindenstrauss](#page-136-3) [\(1975\)](#page-136-3) for an example of the failure of strong convergence in Proposition [5.8.](#page-46-1)

Proposition 5.9. Let $\alpha \in [0, 1]$ and let $T: \mathcal{H} \to \mathcal{H}$ be α -averaged. Suppose that Fix $T \neq \emptyset$, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $]0, 1/(2\alpha)]$ such that inf $n \in \mathbb{N}} \lambda_n > 0$, and

 \Box

let $x_0 \in \mathcal{H}$. Iterate

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = Q(x_0, x_n, x_n + \lambda_n (Tx_n - x_n)), \tag{5.18}
$$

where Q is defined in Lemma [4.6.](#page-33-0) Then $(x_n)_{n \in \mathbb{N}}$ converges strongly to proj_{Fix T} x_0 .

Proof. Define $\mathcal M$ as in [\(3.26\)](#page-27-1), argue as in the proof of Proposition [5.8](#page-46-1) to observe that [\(5.18\)](#page-47-0) is an instance of [\(5.10\)](#page-44-0), and conclude by invoking Theorem [5.3.](#page-44-1) \Box

5.4.3. Resolvent compositions

We focus on the inclusion problem of [Combettes](#page-132-1) [\(2023,](#page-132-1) Section 6), which is modelled by resolvent compositions (see Example [2.40\)](#page-20-2) and solvable via the proximal point algorithm.

Proposition 5.10. Suppose that $L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$ satisfies $0 < ||L|| \leq 1$, let $B: \mathcal{G} \rightarrow$ $2^{\mathcal{G}}$ be maximally monotone, let $V \neq \{0\}$ be a closed vector subspace of H, and let $\gamma \in [0, +\infty]$. Let S be the set of solutions to the problem

find
$$
x \in V
$$
 such that $0 \in B(Lx)$ (5.19)

and let Z be the set of solutions to the problem

find
$$
x \in \mathcal{H}
$$
 such that $0 \in (proj_V \diamond (L \bullet (\gamma B)))x$. (5.20)

Then [\(5.20\)](#page-47-1) is an exact relaxation of [\(5.19\)](#page-47-2) in the sense that $S \neq \emptyset \Rightarrow Z = S$. Now assume that $Z \neq \emptyset$, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $]0,2[$ such that $\sum_{n \in \mathbb{N}} \lambda_n(2-\lambda_n) =$ + ∞ , and let $x_0 \in V$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\ny_n = Lx_n \\
q_n = J_{\gamma B}y_n - y_n \\
z_n = L^* q_n \\
x_{n+1} = x_n + \lambda_n \text{proj}_V z_n.\n\end{cases}
$$
\n(5.21)

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z.

Proof. The exact relaxation claim is established in Theorem 6.3(v) of [Combettes](#page-132-1) [\(2023\)](#page-132-1). Now set $M = \text{proj}_V \circ (L \cdot (\gamma B))$ and note that $|| \text{proj}_V || = 1$ and $\text{proj}_V^* =$ proj_V. Hence, it follows from Example [2.31](#page-18-0) that M is maximally monotone, and from Example [2.40](#page-20-2) that $J_M = \text{proj}_V \circ (\text{Id}_{\mathcal{H}} - L^* \circ L + L^* \circ J_{\gamma B} \circ L) \circ \text{proj}_V$. Altogether, the convergence result follows from Theorem [5.1](#page-42-2)[\(i\)](#page-42-1) \Box

Here is a strongly convergent algorithm based on the Haugazeau variant.

Proposition 5.11. Suppose that $L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$ satisfies $0 < ||L|| \leq 1$, let $B: \mathcal{G} \rightarrow$ $2^{\mathcal{G}}$ be maximally monotone, let $V \neq \{0\}$ be a closed vector subspace of H, and let $\gamma \in [0, +\infty]$. Suppose that the set Z of solutions to the problem

find
$$
x \in \mathcal{H}
$$
 such that $0 \in (proj_V \circ (L \bullet (\gamma B)))x$ (5.22)

is not empty. Let $(\lambda_n)_{n\in\mathbb{N}}$ be a sequence in [0, 1] such that $\inf_{n\in\mathbb{N}} \lambda_n > 0$, and let $x_0 \in V$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\ny_n = Lx_n \\
q_n = J_{\gamma B} y_n - y_n \\
z_n = L^* q_n \\
x_{n+1} = Q(x_0, x_n, x_n + \lambda_n \text{proj}_V z_n),\n\end{cases}
$$
\n(5.23)

where Q is defined in Lemma [4.6.](#page-33-0) Then $(x_n)_{n \in \mathbb{N}}$ converges strongly to proj_Z x_0 .

Proof. Arguing as in the proof of Proposition [5.10,](#page-47-3) this is an application of Theorem [5.3](#page-44-1) with $M = \text{proj}_V \circ (L \bullet (\gamma B))$ and $(\forall n \in \mathbb{N}) \gamma_n = 1$. П.

Below we recover the relaxation framework of [Combettes and Woodstock](#page-133-1) [\(2022\)](#page-133-1) for signal reconstruction in the presence of possibly inconsistent nonlinear observations.

Example 5.12. Let $0 < p \in \mathbb{N}$, let $\gamma \in [0, +\infty)$, and let $V \neq \{0\}$ be a closed vector subspace of H. For every $k \in \{1, \ldots, p\}$, let \mathcal{G}_k be a real Hilbert space, let $L_k \in \mathcal{B}(\mathcal{H}, \mathcal{G}_k)$, let $\omega_k \in]0, +\infty[$, let $F_k : \mathcal{G}_k \to \mathcal{G}_k$ be firmly nonexpansive, and let $r_k \in \mathcal{G}_k$. Consider the nonlinear reconstruction problem [\(Combettes and](#page-133-1) [Woodstock](#page-133-1) [2022,](#page-133-1) Problem 1.1)

find
$$
x \in V
$$
 such that $(\forall k \in \{1, ..., p\}) F_k(L_k x) = r_k$ (5.24)

and the relaxed variational inequality problem [\(Combettes and Woodstock](#page-133-1) [2022,](#page-133-1) Problem 1.3)

find
$$
x \in V
$$
 such that
$$
\sum_{k=1}^{p} \omega_k L_k^*(F_k(L_k x) - r_k) \in V^{\perp}.
$$
 (5.25)

Suppose that $0 < \sum_{k=1}^{p} \omega_k ||L_k||^2 \le 1$ and that [\(5.25\)](#page-48-0) admits solutions. Let $x_0 \in V$, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in]0, 2[such that $\sum_{n \in \mathbb{N}} \lambda_n (2 - \lambda_n) = +\infty$, and iterate

for
$$
n = 0, 1, ...
$$

\nfor $k = 1, ..., p$
\n
$$
\begin{cases}\ny_{k,n} = L_k x_n \\
q_{k,n} = r_k - F_k y_{k,n} \\
z_n = \sum_{k=1}^p \omega_k L_k^* q_{k,n} \\
x_{n+1} = x_n + \lambda_n \text{proj}_V z_n.\n\end{cases}
$$
\n(5.26)

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a solution to [\(5.25\)](#page-48-0).

Proof. Let G be the standard product vector space $\mathcal{G}_1 \times \cdots \times \mathcal{G}_n$, with generic element $y = (y_k)_{1 \leq k \leq p}$, and equipped with the scalar product $(y, y') \mapsto$ $\sum_{k=1}^{p} \omega_k \langle y_k | y'_k \rangle$. Further, set $L: \mathcal{H} \to \mathcal{G}: x \mapsto (L_1 x, \dots, L_p x)$ and

$$
B: \mathcal{G} \to 2^{\mathcal{G}}: \mathbf{y} \mapsto ((\text{Id} - F_1 + r_1)^{-1} y_1 - y_1) \times \cdots \times ((\text{Id} - F_p + r_p)^{-1} y_p - y_p). (5.27)
$$

In this setting, [\(5.24\)](#page-48-1) is a realization of [\(5.19\)](#page-47-2), [\(5.25\)](#page-48-0) of [\(5.20\)](#page-47-1), and [\(5.26\)](#page-48-2) of [\(5.21\)](#page-47-4); for details, see [Combettes](#page-132-1) [\(2023,](#page-132-1) Example 6.10). The claim therefore results from Proposition [5.10.](#page-47-3) \Box

5.4.4. The method of partial inverses

We go back to a formulation already touched upon in Problem [3.10.](#page-25-0) Given a maximally monotone operator $A: \mathcal{H} \to 2^{\mathcal{H}}$ and a closed vector subspace V of H, [Spingarn](#page-142-3) [\(1983\)](#page-142-3) considered the problem

find
$$
x \in V
$$
 and $x^* \in V^{\perp}$ such that $x^* \in Ax$, (5.28)

and solved it by applying the proximal point algorithm to the partial inverse A_V (see Example [2.33\)](#page-18-1). The resulting algorithm is called the *method of partial inverses*. The following is a relaxed version of the convergence result of [Spingarn](#page-142-3) [\(1983,](#page-142-3) Theorem 4.1(i)) (see [Alghamdi](#page-126-0) *et al.* [2014,](#page-126-0) Theorem 2.4).

Theorem 5.13. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be a maximally monotone operator, let V be a closed vector subspace of H, and let $(\lambda_n)_{n\in\mathbb{N}}$ be a sequence in $[0, 2]$ such that $\sum_{n \in \mathbb{N}} \lambda_n (2 - \lambda_n) = +\infty$. Suppose that [\(5.28\)](#page-49-0) has solutions, let $x_0 \in V$, let x_0^* $y_0^* \in V^{\perp}$, and iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n p_n = J_A(x_n + x_n^*) \\
 p_n^* = x_n + x_n^* - p_n \\
 x_{n+1} = x_n - \lambda_n \text{proj}_V p_n^* \\
 x_{n+1}^* = x_n^* - \lambda_n \text{proj}_{V^{\perp}} p_n.\n\end{cases}
$$
\n(5.29)

Then the following hold:

- (i) $proj_V p_n - x_n \to 0$ and $proj_{V^{\perp}} p_n^* - x_n^* \to 0$.
- (ii) There exists a solution (x, x^*) to [\(5.28\)](#page-49-0) such that $x_n \to x$ and $x_n^* \to x^*$.

Proof. Set

$$
(\forall n \in \mathbb{N}) \quad z_n = x_n + x_n^* \tag{5.30}
$$

and note that, since $(x_n)_{n \in \mathbb{N}}$ lies in V and $(x_n^*)_{n \in \mathbb{N}}$ lies in V^{\perp} , [\(5.29\)](#page-49-1) can be rewritten as

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n p_n = J_A(x_n + x_n^*) \\
 p_n^* = x_n + x_n^* - p_n \\
 x_{n+1} = x_n + \lambda_n(\text{proj}_V p_n - x_n) \\
 x_{n+1}^* = x_n^* + \lambda_n(\text{proj}_{V^{\perp}} p_n^* - x_n^*).\n\end{cases}
$$
\n(5.31)

Thus,

$$
(\forall n \in \mathbb{N}) \quad \text{proj}_V \left(\frac{z_{n+1} - z_n}{\lambda_n} + z_n \right) + \text{proj}_{V^{\perp}} \left(z_n - \left(\frac{z_{n+1} - z_n}{\lambda_n} + z_n \right) \right)
$$
\n
$$
= \text{proj}_V \left(\frac{z_{n+1} - z_n}{\lambda_n} + z_n \right) + \text{proj}_{V^{\perp}} \left(\frac{z_n - z_{n+1}}{\lambda_n} \right)
$$
\n
$$
= \text{proj}_V \left(\frac{x_{n+1} - x_n}{\lambda_n} + x_n \right) + \text{proj}_{V^{\perp}} \left(\frac{x_n^* - x_{n+1}^*}{\lambda_n} \right)
$$
\n
$$
= \text{proj}_V p_n + \text{proj}_{V^{\perp}} (x_n^* - p_n^*)
$$
\n
$$
= \text{proj}_V p_n + \text{proj}_{V^{\perp}} (p_n - x_n)
$$
\n
$$
= p_n
$$
\n
$$
= J_A z_n. \tag{5.32}
$$

Hence, it follows from [\(5.30\)](#page-49-2), [\(5.31\)](#page-49-3) and Example [2.38](#page-20-3) that

$$
(\forall n \in \mathbb{N}) \quad z_{n+1} = z_n + \lambda_n (J_{A_V} z_n - z_n). \tag{5.33}
$$

Altogether, we derive from Theorem [5.1\(](#page-42-2)[i\)](#page-42-1) that

$$
J_{A_V} z_n - z_n \to 0 \tag{5.34}
$$

and that there exists $z \in \text{zer } A_V$ such that

$$
z_n \rightharpoonup z. \tag{5.35}
$$

[\(i\)](#page-49-4) In view of [\(5.31\)](#page-49-3), [\(5.30\)](#page-49-2), Example [2.38](#page-20-3) and [\(5.34\)](#page-50-0), we have

$$
\text{proj}_V p_n - x_n = \text{proj}_V (J_{A_V} z_n) - x_n = \text{proj}_V (J_{A_V} z_n - z_n) \to 0 \tag{5.36}
$$

and

$$
x_n^* - \text{proj}_{V^\perp} p_n^* = \text{proj}_{V^\perp}(p_n - x_n) = \text{proj}_{V^\perp} J_A z_n = \text{proj}_{V^\perp}(z_n - J_{A_V} z_n) \to 0. \tag{5.37}
$$

[\(ii\)](#page-49-5) As seen above, $z \in \text{zer } A_V$. Now set $(x, x^*) = (\text{proj}_V z, \text{proj}_{V^{\perp}} z)$. Then Example [2.33](#page-18-1)[\(ii\)](#page-18-2) guarantees that (x, x^*) solves [\(5.28\)](#page-49-0). In addition, since $proj_V$ and proj_{V⊥} are linear and continuous, they are weakly continuous. We conclude that $x_n = \text{proj}_V z_n \longrightarrow \text{proj}_V z = x \text{ and } x_n^* = \text{proj}_{V^\perp} z_n \longrightarrow \text{proj}_{V^\perp} z = x^*.$ \Box

Example 5.14. In Theorem [5.13,](#page-49-6) let $f \in \Gamma_0(\mathcal{H})$ be such that $0 \in \text{sr}(\text{dom } f - V)$, set $A = \partial f$, and suppose that f admits minimizers over V. Then [\(5.28\)](#page-49-0) amounts to finding a solution to the Fenchel dual pair

$$
\underset{x \in V}{\text{minimize}} \quad f(x) \quad \text{and} \quad \underset{x^* \in V^{\perp}}{\text{minimize}} \quad f^*(x^*). \tag{5.38}
$$

In this case, given $x_0 \in V$ and x_0^* $_0^* \in V^{\perp}$, the method of partial inverses [\(5.29\)](#page-49-1) iterates

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n p_n = \text{prox}_f (x_n + x_n^*) \\
 p_n^* = x_n + x_n^* - p_n \\
 x_{n+1} = x_n - \lambda_n \text{proj}_V p_n^* \\
 x_{n+1}^* = x_n^* - \lambda_n \text{proj}_{V^\perp} p_n,\n\end{cases}
$$
\n(5.39)

and Theorem [5.13\(](#page-49-6)[ii\)](#page-49-5) guarantees that there exists a primal–dual solution (x, x^*) of [\(5.38\)](#page-50-1) such that $x_n \rightharpoonup x$ and $x_n^* \rightharpoonup x^*$.

Algorithm [\(5.29\)](#page-49-1) has many applications in convex optimization, for example [Idrissi, Lefebvre and Michelot](#page-137-2) [\(1989\)](#page-137-2), [Lemaire](#page-138-1) [\(1989\)](#page-138-1), [Lenoir and Mahey](#page-138-2) [\(2017\)](#page-138-2), [Pennanen](#page-140-0) [\(2002\)](#page-140-0) and [Spingarn](#page-142-3) [\(1983,](#page-142-3) [1985,](#page-142-4) [1987\)](#page-143-0). As shown in [Rockafellar and](#page-142-5) [Sun](#page-142-5) [\(2019\)](#page-142-5), it also constitutes the basic building block of the *progressive hedging algorithm* in stochastic programming [\(Rockafellar and Wets](#page-142-6) [1991\)](#page-142-6).

Although the method of partial inverses [\(5.29\)](#page-49-1) is presented in the context of the simple problem [\(5.28\)](#page-49-0), it has far-reaching ramifications. Below we present an application proposed in [Alghamdi](#page-126-0) *et al.* [\(2014\)](#page-126-0), where it is applied to Problem [3.11.](#page-26-0) In terms of Framework [1.2,](#page-4-0) this approach can be seen as a rephrasing of Problem [3.11](#page-26-0) as an instance of [\(5.28\)](#page-49-0) in $\mathbf{X} = \mathcal{H} \oplus \mathcal{G}_1 \oplus \cdots \oplus \mathcal{G}_n$.

Proposition 5.15. Let $0 < p \in \mathbb{N}$, let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, and, for every $k \in \{1 \ldots, p\}$, let \mathcal{G}_k be a real Hilbert space, let $B_k : \mathcal{G}_k \to 2^{\mathcal{G}_k}$ be maximally monotone, and let $L_k \in \mathcal{B}(\mathcal{H}, \mathcal{G}_k)$. Suppose that the set Z of solutions to the inclusion

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + \sum_{k=1}^{p} L_k^*(B_k(L_k x))$ (5.40)

is not empty and let Z^* be the set of solutions to the dual inclusion

find
$$
y_1^* \in G_1, ..., y_p^* \in G_p
$$
 such that
\n
$$
\left(\exists x \in A^{-1}\left(-\sum_{k=1}^p L_k^* y_k^*\right)\right) (\forall k \in \{1, ..., p\}) L_k x \in B_k^{-1} y_k^*.
$$
\n(5.41)

Let $x_0 \in \mathcal{H}$ and let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $]0,2[$ such that $\sum_{n \in \mathbb{N}} \lambda_n(2-\lambda_n) = +\infty$. Set

$$
U = \left(\mathrm{Id} + \sum_{k=1}^{p} L_k^* \circ L_k\right)^{-1} \tag{5.42}
$$

and, for every $k \in \{1, ..., p\}$, let $y_{k,0}^* \in \mathcal{G}_k$ and set $y_{k,0} = L_k x_0$. Additionally, set

$$
x_0^* = -\sum_{k=1}^p L_k^* y_{k,0}^*,\tag{5.43}
$$

and iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n p_n = J_A(x_n + x_n^*) \\
 p_n^* = x_n + x_n^* - p_n \\
 \text{for } k = 1, ..., p \\
 q_{k,n} = J_{B_k}(y_{k,n} + y_{k,n}^*) \\
 q_{k,n}^* = y_{k,n} + y_{k,n}^* - q_{k,n} \\
 t_n = U(p_n^* + \sum_{k=1}^p L_k^* q_{k,n}^*) \\
 w_n = U(p_n + \sum_{k=1}^p L_k^* q_{k,n}) \\
 x_{n+1} = x_n - \lambda_n t_n \\
 x_{n+1}^* = x_n^* + \lambda_n (w_n - p_n) \\
 \text{for } k = 1, ..., p \\
 y_{k,n+1} = y_{k,n}^* - \lambda_n L_k t_n \\
 y_{k,n+1}^* = y_{k,n}^* + \lambda_n (L_k w_n - q_{k,n}).\n\end{cases} (5.44)
$$

Then there exist $x \in Z$ and $(y_k^*)_{1 \leq k \leq p} \in Z^*$ such that $x_n \to x$ and, for every $k \in \{1, ..., p\}, y_{k,n}^* \to y_k^*.$

Proof. Define

J.

$$
\begin{cases}\n\mathcal{G} = \mathcal{G}_1 \oplus \cdots \oplus \mathcal{G}_p, \\
B \colon \mathcal{G} \to 2^{\mathcal{G}} \colon (y_1, \ldots, y_p) \mapsto B_1 y_1 \times \cdots \times B_p y_p, \\
L \colon \mathcal{H} \to \mathcal{G} \colon x \mapsto (L_1 x, \ldots, L_p x),\n\end{cases} \tag{5.45}
$$

and note that $L^* \colon \mathcal{G} \to \mathcal{H} \colon (y_1^* \times \mathcal{G})$ $j_1^*,\ldots, y_p^*) \mapsto L_1^*$ $_{1}^{*}y_{1}^{*}$ $i_1^* + \cdots + L_p^* y_p^*$. Moreover set, for every $n \in \mathbb{N}$, $q_n = (q_{k,n})_{1 \leq k \leq p}$, $q_n^* = (q_{k,n}^*)_{1 \leq k \leq p}$, $y_n = (y_{k,n})_{1 \leq k \leq p}$ and $y_n^* = (y_{k,n}^*)_{1 \leq k \leq p}$. In this setting, B is maximally monotone and $J_B: (y_k)_{1 \leq k \leq p} \mapsto$ $(\hat{J}_{B_k} y_k)_{1 \leq k \leq p}$ (Example [2.37\)](#page-20-4), so that [\(5.44\)](#page-52-0) can be rewritten as

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n p_n = J_A(x_n + x_n^*) \\
 q_n = J_B(y_n + y_n^*) \\
 p_n^* = x_n + x_n^* - p_n \\
 q_n^* = y_n + y_n^* - q_n \\
 t_n = U(p_n^* + L^* q_n^*) \\
 w_n = U(p_n + L^* q_n)\n x_{n+1} = x_n - \lambda_n t_n \\
 y_{n+1} = y_n - \lambda_n L t_n \\
 x_{n+1}^* = x_n^* + \lambda_n (w_n - p_n)\n y_{n+1}^* = y_n^* + \lambda_n (Lw_n - q_n).\n\end{cases}
$$
\n(5.46)

Let us introduce

$$
\begin{cases}\n\mathbf{X} = \mathcal{H} \oplus \mathcal{G}, \\
V = \{(x, y) \in \mathbf{X} \mid Lx = y\}, \\
\mathbf{Z} = \{(x, y^*) \in \mathbf{X} \mid -L^*y^* \in Ax \text{ and } y^* \in B(Lx)\}, \\
A: \mathbf{X} \to 2^{\mathbf{X}}: (x, y) \mapsto Ax \times By, \\
\mathbf{S} = \{(x, x^*) \in V \times V^{\perp} \mid x^* \in Ax\},\n\end{cases} (5.47)
$$

and observe that

$$
\begin{cases} V^{\perp} = \{ (x^*, y^*) \in \mathbf{X} \mid x^* = -L^* y^* \}, \\ S = \{ ((x, Lx), (-L^* y^*, y^*)) \in \mathbf{X} \times \mathbf{X} \mid (x, y^*) \in \mathbf{Z} \}. \end{cases}
$$
(5.48)

Then Lemma [3.12](#page-26-1)[\(iii\)](#page-26-2) implies that

$$
(5.40) admits solutions \Leftrightarrow Z \neq \emptyset \Leftrightarrow S \neq \emptyset. \tag{5.49}
$$

Now define $(\forall n \in \mathbb{N})$ $p_n = (p_n, q_n)$, $p_n^* = (p_n^*, q_n^*)$, $x_n = (x_n, y_n)$ and $x_n^* = (x_n^*, q_n^*)$ (x_n^*, y_n^*) . Then $x_0 \in V$ and x_0^* $y_0^* \in V^{\perp}$. Moreover, by Lemma [2.24](#page-16-0) and Example [2.37,](#page-20-4) A is maximally monotone and

$$
(\forall n \in \mathbb{N}) \quad J_A(x_n + x_n^*) = (J_A(x_n + x_n^*), J_B(y_n + y_n^*)). \tag{5.50}
$$

Furthermore, since $U = (\text{Id} + L^* \circ L)^{-1}$, it follows from [\(5.47\)](#page-53-0) and [Bauschke and](#page-127-2) [Combettes](#page-127-2) [\(2017,](#page-127-2) Example 29.19) that

$$
(\forall n \in \mathbb{N}) \quad \text{proj}_{V^{\perp}} \, p_n = (p_n - U(p_n + L^* q_n), q_n - L(U(p_n + L^* q_n))) \tag{5.51}
$$

and

$$
(\forall n \in \mathbb{N}) \quad \text{proj}_V \ p_n^* = (U(p_n^* + L^* q_n^*), L(U(p_n^* + L^* q_n^*))). \tag{5.52}
$$

Combining [\(5.50\)](#page-53-1), [\(5.51\)](#page-53-2) and [\(5.52\)](#page-53-3), we rewrite [\(5.46\)](#page-52-1) as

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n p_n = J_A(x_n + x_n^*) \\
 p_n^* = x_n + x_n^* - p_n \\
 x_{n+1} = x_n - \lambda_n \text{proj}_V p_n^* \\
 x_{n+1}^* = x_n^* - \lambda_n \text{proj}_{V^{\perp}} p_n.\n\end{cases}
$$
\n(5.53)

In turn, Theorem [5.13](#page-49-6)[\(ii\)](#page-49-5) implies that there exists $(x, x^*) \in S$ such that $x_n \to x$ and $x_n^* \rightharpoonup x^*$. We then derive from [\(5.48\)](#page-53-4) that there exists $(x, y^*) \in \mathbb{Z}$ such that $(x_n, y_n^*) \rightharpoonup (x, y^*)$. We complete the proof by invoking Lemma [3.12](#page-26-1)[\(ii\)](#page-26-3). \Box

5.4.5. Renorming

The potency of the proximal point algorithm can be further extended by setting it up in a renormed space. In terms of Framework [1.2,](#page-4-0) the guiding principle lies in the embedding of Example [3.15.](#page-27-2) Here is a weak convergence result.

Proposition 5.16. Let $M: \mathcal{H} \to 2^{\mathcal{H}}$ be a maximally monotone operator such that $Z = \text{zer } M \neq \emptyset$, let $U \in \mathcal{B}(\mathcal{H})$ be a self-adjoint strongly monotone operator, and let X be the real Hilbert space obtained by endowing H with the scalar product $(x, y) \mapsto \langle Ux | y \rangle$. Let $x_0 \in \mathcal{H}$, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $]0, 2[$, and let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $]0, +\infty[$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n u_n = \gamma_n^{-1} U x_n \\
 p_n = (\gamma_n^{-1} U + M)^{-1} u_n \\
 x_{n+1} = x_n + \lambda_n (p_n - x_n),\n\end{cases}
$$
\n(5.54)

and suppose that one of the following holds:

- (i) $\sum_{n \in \mathbb{N}} \lambda_n (2 - \lambda_n) = +\infty$ and $(\forall n \in \mathbb{N}) \gamma_n = 1$.
- (ii) $\sum_{n \in \mathbb{N}} \gamma_n^2 = +\infty$ and $(\forall n \in \mathbb{N}) \lambda_n = 1$.
- (iii) $\inf_{n \in \mathbb{N}} \lambda_n > 0$, $\sup_{n \in \mathbb{N}} \lambda_n < 2$ and $\inf_{n \in \mathbb{N}} \gamma_n > 0$.

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z.

Proof. In view of Lemma [2.25\(](#page-16-1)[ii\)](#page-16-2) and Example [2.39,](#page-20-5) [\(5.54\)](#page-54-0) is just the prox-imal point algorithm [\(5.3\)](#page-42-0) applied to the maximally monotone operator $U^{-1} \circ M$ in X. Since weak convergences in H and X coincide, the claims follow from Lemma [2.25\(](#page-16-1)[i\)](#page-16-3) and Theorem [5.1.](#page-42-2) \Box

Remark 5.17. In terms of the warped resolvent of Section [2.4.3,](#page-21-3) the update in [\(5.54\)](#page-54-0) can be written as $x_{n+1} = x_n + \lambda_n \left(J_{\gamma_n}^U X_n - x_n \right)$.

Likewise, Theorem [5.3](#page-44-1) leads to a strongly convergent algorithm.

Proposition 5.18. Let $M: \mathcal{H} \to 2^{\mathcal{H}}$ be a maximally monotone operator such that $Z = \text{zer } M \neq \emptyset$, let $U \in B(H)$ be a self-adjoint strongly monotone operator, and let X be the real Hilbert space obtained by endowing H with the scalar product $(x, y) \mapsto \langle Ux | y \rangle$. Let $x_0 \in \mathcal{H}$, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in [0, 1] such that $\inf_{n \in \mathbb{N}} \lambda_n > 0$, and let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in]0, +∞[such that $\inf_{n \in \mathbb{N}} \gamma_n > 0$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n u_n = \gamma_n^{-1} U x_n \\
 p_n = (\gamma_n^{-1} U + M)^{-1} u_n \\
 x_{n+1} = \mathsf{Q}(x_0, x_n, x_n + \lambda_n (p_n - x_n)),\n\end{cases}
$$
\n(5.55)

where Q is defined in Lemma [4.6.](#page-33-0) Then $(x_n)_{n \in \mathbb{N}}$ converges strongly to proj_Z x_0 .

Proof. It follows from Lemma [2.25\(](#page-16-1)[ii\)](#page-16-2) and Example [2.39](#page-20-5) that applying the algo-rithm [\(5.10\)](#page-44-0) to the maximally monotone operator $U^{-1} \circ M$ in X yields [\(5.55\)](#page-54-1). Since strong convergences in H and X coincide, the assertion follows from Lemma [2.25\(](#page-16-1)[i\)](#page-16-3) and Theorem [5.3.](#page-44-1) \Box

Although the inversion of the operators $(\gamma_n^{-1}U + M)_{n \in \mathbb{N}}$ in [\(5.54\)](#page-54-0) and [\(5.55\)](#page-54-1) may be intimidating, we show below that the renormed proximal point algorithm leads to important instances of fully executable splitting algorithms. First, we revisit a classical minimization problem and recover an algorithm known as the *proximal Landweber method*.

Example 5.19. Let $\varphi \in \Gamma_0(\mathcal{H})$, let $\mu \in [0, +\infty)$, and let $\gamma \in \mathcal{G}$. Suppose that $0 \neq L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$ and that the set Z of solutions to the optimization problem

$$
\underset{x \in \mathcal{H}}{\text{minimize}} \ \varphi(x) + \frac{\mu}{2} \|Lx - y\|^2 \tag{5.56}
$$

is not empty. Without loss of generality (rescale), assume that $\mu ||L||^2 < 1$. Let $x_0 \in \mathcal{H}$, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $]0,2[$ such that $\sum_{n \in \mathbb{N}} \lambda_n (2 - \lambda_n) = +\infty$, and iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n u_n = x_n - \mu L^*(Lx_n) \\
 p_n = \text{prox}_{\varphi}(u_n + \mu L^*y) \\
 x_{n+1} = x_n + \lambda_n (p_n - x_n).\n\end{cases}
$$
\n(5.57)

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z.

Ī

Proof. Set $f = \varphi - \mu \langle \cdot | L^* y \rangle$, $M = \partial(\varphi + \mu ||L \cdot -y||^2 / 2) = \partial f + \mu L^* \circ L$ and $U = \text{Id} - \mu L^* \circ L$. Then $f \in \Gamma_0(\mathcal{H})$, M is maximally monotone with zer $M = Z$ by virtue of Example [2.12,](#page-13-0) $U \in \mathcal{B}(\mathcal{H})$ is self-adjoint and strongly monotone, and $(U+M)^{-1}$ = prox $_f$ = prox $_{\varphi}$ ($+\mu L^* y$). Consequently, [\(5.57\)](#page-55-0) is the implementation of [\(5.54\)](#page-54-0) with, for every $n \in \mathbb{N}$, $\gamma_n = 1$, and Proposition [5.16](#page-53-5)[\(i\)](#page-54-2) brings the conclusion. \Box

Next, we return to the primal–dual composite inclusion framework of Problem [3.7](#page-24-0) and approach it via Framework [1.2](#page-4-0) where, as discussed in Example [3.20,](#page-29-0) the embedding is based on $X = H \oplus G$ and the Kuhn–Tucker operator K of Lemma [3.8.](#page-24-1)

Example 5.20. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{G} \to 2^{\mathcal{G}}$ be maximally monotone, and let $L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$. Suppose that the set Z of solutions to the primal inclusion

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + L^*(B(Lx))$ (5.58)

is not empty and let Z^* be the set of solutions to the dual inclusion

find
$$
y^* \in \mathcal{G}
$$
 such that $0 \in -L(A^{-1}(-L^*y^*)) + B^{-1}y^*$. (5.59)

Let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $]0,2[$ such that $\sum_{n \in \mathbb{N}} \lambda_n(2 - \lambda_n) = +\infty$, let $x_0 \in \mathcal{H}$,

let y_0^* $\tau_0^* \in \mathcal{G}$, and let $\sigma \in]0, +\infty[$ and $\tau \in]0, +\infty[$ be such that $\tau \sigma ||L||^2 < 1$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nx_n^* = \tau L^* y_n^* \\
p_n = J_{\tau A}(x_n - x_n^*) \\
y_n = \sigma L(2p_n - x_n) \\
q_n^* = J_{\sigma B^{-1}}(y_n^* + y_n) \\
x_{n+1} = x_n + \lambda_n (p_n - x_n) \\
y_{n+1}^* = y_n^* + \lambda_n (q_n^* - y_n^*).\n\end{cases}
$$
\n(5.60)

Then there exist $x \in Z$ and $y^* \in Z^*$ such that $x_n \to x$ and $y^*_n \to y^*$.

Proof. Set $X = H \oplus G$ and

$$
\begin{cases} \mathcal{K}: \mathbf{X} \to 2^{\mathbf{X}}: (x, y^*) \mapsto (Ax + L^*y^*) \times (-Lx + B^{-1}y^*), \\ U: \mathbf{X} \to \mathbf{X}: (x, y^*) \mapsto (\tau^{-1}x - L^*y^*, -Lx + \sigma^{-1}y^*). \end{cases}
$$
(5.61)

As seen in Lemma [3.8](#page-24-1)[\(iii\)](#page-25-1)–[\(iv\)](#page-25-2), κ is the maximally monotone Kuhn–Tucker operator associated with [\(5.58\)](#page-55-1)–[\(5.59\)](#page-55-2), and to prove the claim it is enough to show that $(x_n, y_n^*)_{n \in \mathbb{N}}$ converges weakly to a point in zer K, which we shall derive from Pro-position [5.16\(](#page-53-5)[i\)](#page-54-2). It is clear that $U \in B(X)$ is self-adjoint. Now set $\beta = 1 - \sqrt{\sigma \tau} ||L||$. Then, since $\tau \sigma ||L||^2 < 1, \beta \in]0, 1[$ and, for every $(x, y^*) \in \mathbf{X}$, the Cauchy–Schwarz inequality yields

$$
\langle U(x, y^*) | (x, y^*) \rangle_{\mathbf{X}} = \tau^{-1} ||x||^2 - 2\langle Lx | y^* \rangle + \sigma^{-1} ||y^*||^2
$$

\n
$$
\geq \tau^{-1} ||x||^2 - 2\sqrt{\tau \sigma} ||L|| \left\| \frac{x}{\sqrt{\tau}} \right\| \left\| \frac{y^*}{\sqrt{\sigma}} \right\| + \sigma^{-1} ||y^*||^2
$$

\n
$$
= \tau^{-1} ||x||^2 - 2(1 - \beta) \left\| \frac{x}{\sqrt{\tau}} \right\| \left\| \frac{y^*}{\sqrt{\sigma}} \right\| + \sigma^{-1} ||y^*||^2
$$

\n
$$
= \left(\left\| \frac{x}{\sqrt{\tau}} \right\| - \left\| \frac{y^*}{\sqrt{\sigma}} \right\| \right)^2 + 2\beta \left\| \frac{x}{\sqrt{\tau}} \right\| \left\| \frac{y^*}{\sqrt{\sigma}} \right\|
$$

\n
$$
= (1 - \beta) \left(\left\| \frac{x}{\sqrt{\tau}} \right\| - \left\| \frac{y^*}{\sqrt{\sigma}} \right\| \right)^2 + \beta \left(\left\| \frac{x}{\sqrt{\tau}} \right\|^2 + \left\| \frac{y^*}{\sqrt{\sigma}} \right\|^2 \right)
$$

\n
$$
\geq \beta(\tau^{-1} ||x||^2 + \sigma^{-1} ||y^*||^2)
$$

\n
$$
\geq \beta \min{\tau^{-1}, \sigma^{-1}} ||(x, y^*)||_{\mathbf{x}}^2, \qquad (5.62)
$$

which confirms that U is strongly monotone. It remains to show that (5.60) is a realization of [\(5.54\)](#page-54-0) with the above operators K and U. Define ($\forall n \in \mathbb{N}$) $x_n = (x_n, y_n^*)$, $p_n = (p_n, q_n^*)$ and $u_n = Ux_n$. Then we derive from [\(5.60\)](#page-56-0) and [\(2.18\)](#page-7-1) that

$$
(\forall n \in \mathbb{N}) \quad\n\begin{cases}\n x_n - p_n - \tau L^* y_n^* \in \tau A p_n, \\
 y_n^* - q_n^* + \sigma L (2p_n - x_n) \in \sigma B^{-1} q_n^*.\n\end{cases}\n\tag{5.63}
$$

This yields ($\forall n \in \mathbb{N}$) $u_n - Up_n \in \mathcal{K}p_n$, i.e. $p_n = (U + \mathcal{K})^{-1}u_n$. Altogether, [\(5.60\)](#page-56-0) corresponds to the iteration

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n\mathbf{u}_n = U \mathbf{x}_n \\
\mathbf{p}_n = (U + \mathcal{K})^{-1} \mathbf{u}_n \\
\mathbf{x}_{n+1} = \mathbf{x}_n + \lambda_n (\mathbf{p}_n - \mathbf{x}_n),\n\end{cases}
$$
\n(5.64)

which is precisely [\(5.54\)](#page-54-0) with ($\forall n \in \mathbb{N}$) $\gamma_n = 1$.

Remark 5.21. Here are a few observations regarding Example [5.20.](#page-55-3)

- (i) We have derived weak convergence from Proposition [5.16\(](#page-53-5)[i\)](#page-54-2). Using items [\(ii\)](#page-54-3) or [\(iii\)](#page-54-4) in Proposition [5.16](#page-53-5) leads to alternative forms of [\(5.60\)](#page-56-0) involving proximal parameters $(\gamma_n)_{n \in \mathbb{N}}$.
- (ii) It is straightforward to derive a strongly convergent best approximation variant of [\(5.60\)](#page-56-0) from Proposition [5.18](#page-54-5) by following the same pattern as in the proof of Example [5.20,](#page-55-3) i.e. applying [\(5.55\)](#page-54-1) to the operators $\mathcal K$ and $\mathcal U$ of [\(5.61\)](#page-56-1).
- (iii) Algorithm [\(5.60\)](#page-56-0) can be adapted to Problem [3.11](#page-26-0) by applying it to the setting of [\(5.45\)](#page-52-2) and using Example [2.37.](#page-20-4)
- (iv) Let $f \in \Gamma_0(\mathcal{H})$ and $g \in \Gamma_0(\mathcal{G})$, and set $A = \partial f$ and $B = \partial g$ in Example [5.20,](#page-55-3) which corresponds to the primal–dual minimization setting of Problem [3.9.](#page-25-3) The specialization of Example [5.20](#page-55-3) to this minimization problem appears in [Condat](#page-133-2) [\(2013,](#page-133-2) Theorem 3.2), where [\(5.60\)](#page-56-0) is called the *Chambolle–Pock algorithm* because it collapses to the algorithm proposed in [Chambolle and](#page-131-2) [Pock](#page-131-2) [\(2011,](#page-131-2) Algorithm I) in Euclidean spaces when ($\forall n \in \mathbb{N}$) $\lambda_n = 1$; see [Condat](#page-133-3) *et al.* [\(2023\)](#page-133-3) for variations on this algorithm. The fact that the Chambolle–Pock algorithm is a renormed proximal point algorithm was first observed in [He and Yuan](#page-136-4) [\(2012\)](#page-136-4).

6. Douglas–Rachford splitting

6.1. Preview

The Douglas–Rachford splitting algorithm is an implicit alternating direction method designed in [Douglas and Rachford](#page-134-2) [\(1956\)](#page-134-2) to solve the matrix equation $Ax + Bx = f$, where A and B are positive-definite matrices arising from the discretization of partial differentiation operators. It is described by the iteration process

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nx_{n+1/2} - x_n + Ax_{n+1/2} + Bx_n = f \\
x_{n+1} - x_n + Ax_{n+1/2} + Bx_{n+1} = f.\n\end{cases}
$$
\n(6.1)

[Lieutaud](#page-138-0) [\(1969](#page-138-0)*a*) (see also [Lieutaud](#page-138-3) [1969](#page-138-3)*b*) proposed an infinite-dimensional nonlinear generalization of the method by showing that [\(6.1\)](#page-57-0) can be extended to

 \Box

single-valued hemicontinuous monotone operators with dom $A = \text{dom } B = H$. In particular, he established in [Lieutaud](#page-138-0) [\(1969](#page-138-0)*a*) that, with the additional assumption that A or B is strongly monotone, $(x_n)_{n\in\mathbb{N}}$ converges strongly to some $x \in \mathcal{H}$ which satisfies $Ax + Bx = f$. The investigation of the method for general set-valued maximally monotone operators was initiated in [Lions and Mercier](#page-138-4) [\(1979\)](#page-138-4), with subsequent improvements in [Bauschke and Combettes](#page-127-2) [\(2017\)](#page-127-2), [Bauschke and Moursi](#page-127-3) [\(2017\)](#page-127-3), [Combettes](#page-132-2) [\(2009\)](#page-132-2), [Eckstein and Bertsekas](#page-134-0) [\(1992\)](#page-134-0) and [Svaiter](#page-143-1) [\(2011\)](#page-143-1). See also [Xue](#page-144-0) [\(2023](#page-144-0)*a*) for further analysis.

To chart the path from the original Douglas–Rachford algorithm to its modern version for monotone set-valued operators, let us go back to the matrix setting. Upon eliminating the intermediate variables $(x_{n+1/2})_{n \in \mathbb{N}}$ in [\(6.1\)](#page-57-0) and noting that $AJ_A = Id - J_A$, we obtain

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = J_B(x_n - AJ_A(x_n - Bx_n + f) + f)
$$

= $J_B(Bx_n + J_A(x_n - Bx_n + f)).$ (6.2)

Now set ($\forall n \in \mathbb{N}$) $x_n = J_B y_n$. Then we derive from [\(6.2\)](#page-58-1) that

$$
(\forall n \in \mathbb{N}) \quad y_{n+1} = BJ_B y_n + J_A (J_B y_n - BJ_B y_n + f)
$$

= $y_n - J_B y_n + J_A (2J_B y_n - y_n + f)$, (6.3)

which leads to the recursion

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nx_n = J_B y_n \\
z_n = J_A (2x_n - y_n + f) \\
y_{n+1} = y_n + z_n - x_n.\n\end{cases}
$$
\n(6.4)

 As noted in [Lions and Mercier](#page-138-4) [\(1979\)](#page-138-4), unlike [\(6.1\)](#page-57-0), this algorithm is well defined for arbitrary maximally monotone set-valued operators and is now referred to as the Douglas–Rachford splitting algorithm in this context.

Remark 6.1. In particular, upon setting $B = 0$ and $f = 0$ in [\(6.4\)](#page-58-2) and assuming that $A: \mathcal{H} \to \mathcal{H}$ is hemicontinuous and strongly monotone, it follows from Lieutaud's result [\(Lieutaud](#page-138-0) [1969](#page-138-0)*a*) that the sequence $(x_n)_{n \in \mathbb{N}}$ generated by the recursion

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = J_A x_n \tag{6.5}
$$

converges strongly to a zero of A. This is actually the first instance of convergence of the proximal point algorithm, which has been attributed to later work in the literature. The case when A and B are gradients of convex functions was also considered in [Lieutaud](#page-138-0) [\(1969](#page-138-0)*a*) in connection with the minimization of the sum of two differentiable convex functions.

6.2. Weak convergence

We present results for a form of the Douglas–Rachford algorithm (6.4) which includes relaxation parameters and a dual inclusion problem.

Theorem 6.2. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $]0,2[$ such that $\sum_{n \in \mathbb{N}} \lambda_n (2 - \lambda_n) = +\infty$, and let $\gamma \in [0, +\infty]$. Suppose that the set Z of solutions to the inclusion

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + Bx$ (6.6)

is not empty and let Z^* be the set of solutions to the dual problem

find
$$
x^* \in \mathcal{H}
$$
 such that $0 \in -A^{-1}(-x^*) + B^{-1}x^*$. (6.7)

Let $y_0 \in \mathcal{H}$ and iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n x_n = J_{\gamma B} y_n \\
 x_n^* = \gamma^{-1} (y_n - x_n) \\
 z_n = J_{\gamma A} (2x_n - y_n) \\
 y_{n+1} = y_n + \lambda_n (z_n - x_n).\n\end{cases}
$$
\n(6.8)

Then there exists $y \in \mathcal{H}$ such that $y_n \to y$. Now set $x = J_{\gamma}$ and $x^* = \gamma By$. Then the following hold:

- (i) $x_n \to x \in Z$.
- (ii) $x_n^* \rightharpoonup x^* \in Z^*$.

Proof. We rely on the embedding of Example [3.17.](#page-28-0) Set

$$
R_{\gamma A} = 2J_{\gamma A} - \text{Id}, \quad R_{\gamma B} = 2J_{\gamma B} - \text{Id} \quad \text{and} \quad \mathcal{M} = \left(\frac{R_{\gamma A} \circ R_{\gamma B} + \text{Id}}{2}\right)^{-1} - \text{Id}.
$$

Then it follows from [\(2.33\)](#page-8-2) and Lemma [2.34\(](#page-20-0)[iii\)](#page-20-1) that $(R_{\gamma A} \circ R_{\gamma B} + \text{Id})/2$ is firmly nonexpansive and that M is maximally monotone. In addition, Proposition 26.1(iii)(b) of [Bauschke and Combettes](#page-127-2) [\(2017\)](#page-127-2) asserts that

$$
\varnothing \neq Z = J_{\gamma B}(\text{zer } \mathcal{M}),\tag{6.10}
$$

while Proposition $26.1(iii)(c)$ of [Bauschke and Combettes](#page-127-2) [\(2017\)](#page-127-2) asserts that

$$
\varnothing \neq Z^* = {}^{\gamma}B(\text{zer } \mathcal{M}).\tag{6.11}
$$

Furthermore, we derive from [\(6.8\)](#page-59-0) and [\(6.9\)](#page-59-1) that

$$
(\forall n \in \mathbb{N}) \quad y_{n+1} = y_n + \frac{\lambda_n}{2} (R_{\gamma A}(R_{\gamma B}y_n) - y_n) = y_n + \lambda_n (J_{\mathcal{M}}y_n - y_n), \quad (6.12)
$$

that is, $(y_n)_{n \in \mathbb{N}}$ is constructed by the proximal point algorithm [\(5.3\)](#page-42-0) for M. Since [\(6.10\)](#page-59-2) implies that zer $\mathcal{M} \neq \emptyset$, Theorem [5.1\(](#page-42-2)[i\)](#page-42-1) asserts that

$$
J_{\mathcal{M}}y_n - y_n \to 0
$$
 and $(\exists y \in \text{zer}\,\mathcal{M})$ $y_n \to y.$ (6.13)

In turn, [\(6.10\)](#page-59-2) yields $x = J_{\gamma B} y \in Z$, while [\(6.8\)](#page-59-0) yields

$$
z_n - x_n = J_{\gamma A}(2x_n - y_n) - x_n = J_{\mathcal{M}} y_n - y_n \to 0.
$$
 (6.14)

[\(i\)](#page-59-3) Let us set

$$
(\forall n \in \mathbb{N}) \quad z_n^* = \gamma^{-1} (2x_n - y_n - z_n). \tag{6.15}
$$

Then [\(6.8\)](#page-59-0) and [\(2.18\)](#page-7-1) yield

$$
(\forall n \in \mathbb{N}) \quad \begin{cases} (z_n, z_n^*) \in \text{gra } A, \\ (x_n, x_n^*) \in \text{gra } B, \\ x_n - z_n = \gamma (x_n^* + z_n^*). \end{cases} \tag{6.16}
$$

Since Lemma [2.34\(](#page-20-0)[iii\)](#page-20-1) asserts that $J_{\gamma B}$ is nonexpansive,

$$
(\forall n \in \mathbb{N}) \quad ||x_n - x_0|| = ||J_{\gamma B}y_n - J_{\gamma B}y_0|| \le ||y_n - y_0||. \tag{6.17}
$$

Hence, since $(y_n)_{n \in \mathbb{N}}$ is bounded, so is $(x_n)_{n \in \mathbb{N}}$. Now take $z \in \mathfrak{W}(x_n)_{n \in \mathbb{N}}$, say $x_{k_n} \to z$. Then it follows from [\(6.14\)](#page-59-4), [\(6.13\)](#page-59-5), [\(6.15\)](#page-60-0) and [\(6.16\)](#page-60-1) that

$$
z_{k_n} \rightharpoonup z
$$
, $z_{k_n}^* \rightharpoonup \gamma^{-1}(z - y)$, $z_n - x_n \rightharpoonup 0$ and $z_n^* + x_n^* = \gamma^{-1}(x_n - z_n) \rightharpoonup 0$. (6.18)

In turn, Lemma [2.50](#page-23-0) yields $z \in \text{zer}(A + B) = Z$,

$$
(z, \gamma^{-1}(z - y)) \in \text{gra } A
$$
 and $(z, \gamma^{-1}(y - z)) \in \text{gra } B.$ (6.19)

Hence, [\(2.18\)](#page-7-1) implies that

$$
z = J_{\gamma B} y. \tag{6.20}
$$

Thus, $x = J_{\gamma}g y$ is the unique weak sequential cluster point of the bounded sequence $(x_n)_{n \in \mathbb{N}}$ and therefore, by Lemma [4.1](#page-30-3)[\(ii\)](#page-30-4), $x_n \to x$.

[\(ii\)](#page-59-6) We have $y_n \to y \in \text{zer } M$ and, by [\(i\)](#page-59-3), $x_n \to x$. Hence, $x_n^* = \gamma^{-1}(y_n - x_n) \to$ $\gamma^{-1}(y - x) = \gamma B y = x^*$. In view of [\(6.11\)](#page-59-7), the proof is complete.

Remark 6.3. The convergence result of [Lions and Mercier](#page-138-4) [\(1979\)](#page-138-4) is that, for the unrelaxed scheme [\(6.4\)](#page-58-2), $(y_n)_{n \in \mathbb{N}}$ converges weakly to a point $y \in \mathcal{H}$ such that J_{γ} _B $y \in Z$; see [Combettes](#page-132-3) [\(2004\)](#page-132-3) and [Eckstein and Bertsekas](#page-134-0) [\(1992\)](#page-134-0) for the relaxed case. In the special case when $J_{\gamma B}$ is weakly sequentially continuous, as is the case when H is finite-dimensional, $x_n = J_{\gamma B} y_n \rightarrow J_{\gamma B} y \in Z$. The key fact that $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in $zer(A + B)$ without any further assumption was first proved in [Svaiter](#page-143-1) [\(2011\)](#page-143-1) in the unrelaxed case. Theorem [6.2](#page-58-3) was established in [Bauschke and Combettes](#page-127-2) [\(2017,](#page-127-2) Theorem 26.11). The component of the proof given above up to [\(6.13\)](#page-59-5) exploits an idea from [Eckstein and Bertsekas](#page-134-0) [\(1992\)](#page-134-0), that identifies the core iteration of [\(6.8\)](#page-59-0) as an instantiation of the proximal point algorithm.

Remark 6.4. Connections between the Douglas–Rachford algorithms and the method of partial inverses of Section [5.4.4](#page-49-7) are discussed in [Lawrence and Spingarn](#page-138-5) [\(1987,](#page-138-5) Section 1); see also [Eckstein and Bertsekas](#page-134-0) [\(1992,](#page-134-0) Section 5) and [Mahey, Oualibouch and Dinh Tao](#page-138-6) [\(1995\)](#page-138-6). Let us show that we can actually

derive Theorem [5.13](#page-49-6)[\(ii\)](#page-49-5) from Theorem [6.2.](#page-58-3) Let $(x_n)_{n \in \mathbb{N}}$, $(x_n^*)_{n \in \mathbb{N}}$, $(p_n)_{n \in \mathbb{N}}$ and $(p_n^*)_{n \in \mathbb{N}}$ be the sequence generated by [\(5.29\)](#page-49-1) and set $(\forall n \in \mathbb{N})$ $y_n = x_n + x_n^*$ and $z_n = \text{proj}_V(2p_n - y_n)$. Then [\(5.29\)](#page-49-1) yields

$$
(\forall n \in \mathbb{N}) \text{ proj}_V p_n^* + \text{proj}_{V^{\perp}} p_n = \text{proj}_V (y_n - p_n) + p_n - \text{proj}_V p_n = p_n - z_n. (6.21)
$$

Altogether,

$$
(\forall n \in \mathbb{N}) \quad p_n = J_A y_n, \quad z_n = \text{proj}_V (2p_n - y_n) \quad \text{and} \quad y_{n+1} = y_n + \lambda_n (z_n - p_n). \tag{6.22}
$$

In view of Example [2.36,](#page-20-6) this recursion is precisely that of [\(6.8\)](#page-59-0) for the operators (N_V, A) with $\gamma = 1$. We therefore derive the following from Theorem [6.2:](#page-58-3) $(y_n)_{n \in \mathbb{N}}$ converges weakly to a point $y \in \mathcal{H}$ and, if we set $x = J_A y$ and $x^* = y - J_A y$, then $p_n \to x \in \text{zer}(N_V + A)$ and, by Example [2.15,](#page-13-1) $p_n^* \to x^* \in \text{zer}(N_V + A^{-1})$. Furthermore, (6.19) – (6.20) implies that $(x, -x^*) = (x, x - y) \in \text{gra } N_V$ and $(x, x^*) =$ $(x, y - x) \in \text{gra } A$. Thus, Example [2.15](#page-13-1) yields $(x, x^*) \in \text{gra } N_V \cap \text{gra } A$ and (x, x^*) therefore solves (5.28) . Finally, since equation (11) of Combettes (2009) asserts that $J_A y = \text{proj}_V y$ and since proj_V is weakly continuous, we have $x_n = \text{proj}_V (x_n + x_n^*) =$ proj_V $y_n \to \text{proj}_V$ $y = x$ and $x_n^* = \text{proj}_{V^{\perp}} y_n \to \text{proj}_{V^{\perp}} y = y - \text{proj}_V$ $y = x^*$. Let us add that, in this setting, the operator $\mathcal M$ of [\(6.9\)](#page-59-1) is just the partial inverse A_V .

Remark 6.5. The many application areas of the Douglas–Rachford algorithm (in its original two-operator form or transposed in product spaces) include road design [\(Bauschke, Koch and Phan](#page-128-3) [2016\)](#page-128-3), equilibrium problems [\(Briceño-Arias](#page-129-1) [2012\)](#page-129-1), biostatistics [\(Combettes and Müller](#page-133-4) [2021\)](#page-133-4), signal recovery [\(Combettes and](#page-133-5) [Pesquet](#page-133-5) [2007\)](#page-133-5), traffic theory [\(Fukushima](#page-135-1) [1996\)](#page-135-1), noise removal [\(Steidl and Teuber](#page-143-2) [2010\)](#page-143-2) and compressive sensing [\(Yu, Peng, Han and Cui](#page-144-1) [2017\)](#page-144-1); see also [Lindstrom](#page-138-7) [and Sims](#page-138-7) [\(2021\)](#page-138-7) for additional references.

6.3. Strong convergence

As shown in [Bùi and Combettes](#page-130-1) [\(2020](#page-130-1)*a*, Counterexample 2), the convergence of $(x_n)_{n \in \mathbb{N}}$ in Theorem [6.2\(](#page-58-3)[i\)](#page-59-3) is only weak. The following version based on Theorem [5.3](#page-44-1) furnishes strong convergence.

Theorem 6.6. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, suppose that zer($A + B$) ≠ \emptyset , let $y_0 \in \mathcal{H}$, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in [0, 1] such that inf_{$n \in \mathbb{N}$} $\lambda_n > 0$, and let $\gamma \in]0, +\infty[$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nx_n = J_{\gamma B} y_n \\
x_n^* = \gamma^{-1} (y_n - x_n) \\
z_n = J_{\gamma A} (2x_n - y_n) \\
y_{n+1} = Q(y_0, y_n, y_n + \lambda_n (z_n - x_n)),\n\end{cases}
$$
\n(6.23)

where Q is defined in Lemma [4.6.](#page-33-0) Let Z and Z^* be the sets of solutions to [\(6.6\)](#page-59-8)

and [\(6.7\)](#page-59-9), respectively. Then the following hold:

- (i) $(x_n)_{n \in \mathbb{N}}$ converges strongly to a point in Z.
- (ii) $(x_n^*)_{n \in \mathbb{N}}$ converges strongly to a point in Z^* .

Proof. Define M as in [\(6.9\)](#page-59-1) and set $y = \text{proj}_{\text{zer}} M y_0$, $x = J_{\gamma} y_0$ and $x^* =$ $\gamma^{-1}(y-x)$. Then it follows from [\(6.10\)](#page-59-2) that $x \in Z$ and from [\(6.11\)](#page-59-7) that $x^* \in Z^*$. Additionally, we derive from [\(6.23\)](#page-61-0) that

$$
(\forall n \in \mathbb{N}) \quad y_{n+1} = \mathsf{Q}(y_0, y_n, y_n + \lambda_n (J_{\mathcal{M}} y_n - y_n)). \tag{6.24}
$$

Hence, Theorem [5.3](#page-44-1) yields $y_n \to y$ and, by continuity of $J_{\gamma B}$, $x_n = J_{\gamma B} y_n \to$ $J_{\gamma B} y = x$. Finally, $x_n^* = \gamma^{-1}(y_n - x_n) \rightarrow \gamma^{-1}(y - x) = x^*$.

Remark 6.7. The method of partial inverses of Theorem [5.13](#page-49-6) may converge only weakly [\(Bùi and Combettes](#page-130-1) [2020](#page-130-1)*a*, Counterexample 4). A strongly convergent version can be designed using Remark [6.4](#page-60-4) and Theorem [6.6.](#page-61-1)

6.4. Special cases and variants

6.4.1. Minimization setting

We illustrate an application of the Douglas–Rachford algorithm to primal–dual minimization.

Example 6.8. Let $f \in \Gamma_0(\mathcal{H})$ and $g \in \Gamma_0(\mathcal{H})$ be such that $Z = \text{Argmin}(f+g) \neq \emptyset$ and 0 ∈ sri(dom f – dom g). Set Z^* = Argmin ($f^* \circ (-Id) + g^*$), let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $]0,2[$ such that $\sum_{n\in\mathbb{N}} \lambda_n(2-\lambda_n) = +\infty$, let $\gamma \in]0,+\infty[$, let $y_0 \in \mathcal{H}$, and iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n x_n = \text{prox}_{\gamma g} y_n \\
 x_n^* = \gamma^{-1} (y_n - x_n) \\
 z_n = \text{prox}_{\gamma f} (2x_n - y_n) \\
 y_{n+1} = y_n + \lambda_n (z_n - x_n).\n\end{cases}
$$
\n(6.25)

Then it follows from Problem [3.9,](#page-25-3) Example [2.35](#page-20-7) and Theorem [6.2](#page-58-3) that there exists $(x, x^*) \in Z \times Z^*$ such that $x_n \to x$ and $x_n^* \to x^*$.

Remark 6.9. Relations between the Douglas–Rachford algorithm [\(6.25\)](#page-62-0) and other methods have been noted in the literature.

(i) It is observed in [Condat](#page-133-2) [\(2013,](#page-133-2) Section 3.1.1) that the Douglas–Rachford algorithm [\(6.25\)](#page-62-0) can be viewed as a limiting case of the Chambolle–Pock algorithm (see Remark [5.21\(](#page-57-1)[iv\)](#page-57-2)) by implementing it in the case when $G =$ $H, L = \text{Id}$ and $\sigma = 1/\tau = \gamma$. Note, however, that this setting violates the condition $\tau \sigma ||L||^2$ < 1 used to prove weak convergence of [\(5.60\)](#page-56-0) in Example [5.20.](#page-55-3)

(ii) Consider the setting of Problem [3.9](#page-25-3) and note that the primal minimization problem [\(3.12\)](#page-25-4) is equivalent to

$$
\underset{(x,y)\in\text{gra}\,L}{\text{minimize}}\ f(x) + g(y). \tag{6.26}
$$

The (unscaled) *augmented Lagrangian* associated with [\(6.26\)](#page-63-0) is the saddle function (see Example [2.21\)](#page-15-0) on $(\mathcal{H} \oplus \mathcal{G}) \oplus \mathcal{G}$ defined as

$$
F: \mathcal{H} \oplus \mathcal{G} \oplus \mathcal{G} \to]-\infty, +\infty]
$$

$$
(x, y, v^*) \mapsto f(x) + g(y) + \langle Lx - y | v^* \rangle + \frac{1}{2} ||Lx - y||^2.
$$
 (6.27)

Iteration n of the alternating-direction method of multipliers (ADMM) consists in minimizing F over x for y_n and v_n^* fixed to get x_n , then over y for x_n and v_n^* fixed to get y_{n+1} , and then applying a proximal maximization step with respect to the Lagrange multiplier v^* for x_n and y_{n+1} fixed to get v_{n+1}^* . It was originally proposed in [Glowinski and Marrocco](#page-136-5) [\(1974\)](#page-136-5), refined in [Gabay and](#page-135-2) [Mercier](#page-135-2) [\(1976\)](#page-135-2), and further developed in [Boyd](#page-129-2) *et al.* [\(2010\)](#page-129-2), [Eckstein and](#page-134-0) [Bertsekas](#page-134-0) [\(1992\)](#page-134-0), [Gabay](#page-135-0) [\(1983\)](#page-135-0) and [Glowinski and Le Tallec](#page-136-6) [\(1989\)](#page-136-6). Given $y_0 \in \mathcal{G}$ and v_0^* $\hat{O}_0 \in \mathcal{G}$, ADMM iterates

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n x_n \in \text{Argmin} \quad \left(f(x) + \langle Lx | v_n^* \rangle + \frac{1}{2} ||Lx - y_n||^2 \right) \\
 d_n = Lx_n \\
 y_{n+1} = \underset{y \in \mathcal{G}}{\text{argmin}} \quad \left(g(y) - \langle y | v_n^* \rangle + \frac{1}{2} ||d_n - y||^2 \right) \\
 v_{n+1}^* = v_n^* + d_n - y_{n+1}.\n\end{cases}
$$
\n(6.28)

It should be emphasized that ADMM is not a splitting algorithm in our sense since the computation of x_n involves a minimization step which does not separate f and L , and can therefore be hard to execute. This step is also setvalued in general. Nonetheless, [\(6.28\)](#page-63-1) can be interpreted as an application of the Douglas–Rachford algorithm [\(6.25\)](#page-62-0) to the functions $f^* \circ (-L^*)$ (here again, note that f and L are not separated and that the typically non-explicit operator $prox_{f^* \circ (-L^*)}$ intervenes) and g^* present in the dual problem [\(3.13\)](#page-25-5) [\(Gabay](#page-135-0) [1983\)](#page-135-0); see also [Eckstein and Bertsekas](#page-134-0) [\(1992\)](#page-134-0). This is merely an algorithmic identification and not a claim that ADMM converges. Convergence requires more restrictions on the problem, for instance finite-dimensionality of H and G and invertibility of $L^* \circ L$ in [Eckstein and Bertsekas](#page-134-0) [\(1992,](#page-134-0) Section 5). For further analysis, see [Banert, Boţ and Csetnek](#page-127-4) [\(2021\)](#page-127-4), [Boţ and Csetnek](#page-129-3) [\(2019\)](#page-129-3) and [Ryu, Liu and Yin](#page-142-7) [\(2019\)](#page-142-7).

6.4.2. Peaceman–Rachford splitting

The first implicit alternating direction method [\(Birkhoff and Varga](#page-128-4) [1959\)](#page-128-4) to solve the positive-definite matrix equation $Ax + Bx = f$ is the Peaceman–Rachford

algorithm [\(Peaceman and Rachford](#page-140-1) [1955;](#page-140-1) see also [Douglas](#page-134-3) [1955\)](#page-134-3). It is described by the iterative process

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n x_{n+1/2} - x_n + Ax_{n+1/2} + Bx_n = f \\
 x_{n+1} - x_{n+1/2} + Ax_{n+1/2} + Bx_{n+1} = f.\n\end{cases}
$$
\n(6.29)

Using the same arguments used to transition from (6.1) to (6.4) , we rewrite (6.29) as

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nx_n = J_B y_n \\
z_n = J_A (2x_n - y_n + f) \\
y_{n+1} = y_n + 2(z_n - x_n).\n\end{cases}
$$
\n(6.30)

The strong convergence of $(x_n)_{n \in \mathbb{N}}$ to a solution to the equation $Ax + Bx = f$, where A and B are single-valued hemicontinuous monotone operators such that $dom A = dom B = H$ and B is strongly monotone, was established in [Lieutaud](#page-138-0) [\(1969](#page-138-0) a) and, with the additional assumption that H is finite-dimensional and the operators are continuous, in [Kellogg](#page-137-3) [\(1969\)](#page-137-3).

Algorithm [\(6.30\)](#page-64-1) was first considered for general maximally monotone setvalued operators A and B in [Lions and Mercier](#page-138-4) [\(1979\)](#page-138-4). In the presence of a scaling parameter $\gamma \in [0, +\infty)$ and taking $f = 0$ without loss of generality, the Peaceman–Rachford algorithm becomes

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nx_n = J_{\gamma B} y_n \\
z_n = J_{\gamma A} (2x_n - y_n) \\
y_{n+1} = y_n + 2(z_n - x_n).\n\end{cases}
$$
\n(6.31)

Upon defining $\mathcal M$ as in [\(6.9\)](#page-59-1), we derive from [\(6.31\)](#page-64-2) that

$$
(\forall n \in \mathbb{N}) \quad y_{n+1} = (2J_{\mathcal{M}} - \text{Id})y_n. \tag{6.32}
$$

We can view (6.31) as a limiting case of the Douglas–Rachford algorithm (6.8) in which the relaxation parameters $(\lambda_n)_{n \in \mathbb{N}}$ are allowed to be 2. This, of course, means that [\(6.31\)](#page-64-2) operates outside of the setting of Theorem [5.1](#page-42-2) and hence of the geometric framework of Theorem [4.2.](#page-30-0) As a result, the weak convergence of $(y_n)_{n \in \mathbb{N}}$ cannot be guaranteed without additional assumptions since [\(6.32\)](#page-64-3) amounts to iterating a merely nonexpansive operator; see [Lions and Mercier](#page-138-4) [\(1979,](#page-138-4) Remark 6) for a counterexample. Strong convergence of $(x_n)_{n \in \mathbb{N}}$ to a point in zer($A + B$) takes place when B is strongly monotone [\(Lions and Mercier](#page-138-4) [1979,](#page-138-4) Remark 2). More generally, strong convergence occurs when B is uniformly monotone on bounded sets or when int Fix $(2J_{\gamma A} -Id)(2J_{\gamma B} -Id) \neq \emptyset$ [\(Combettes](#page-132-2) [2009,](#page-132-2) Remark 2.2(iv)).

6.4.3. A three-operator splitting algorithm

An extension of the Douglas–Rachford algorithm [\(6.8\)](#page-59-0) was proposed in [Davis and](#page-134-4) [Yin](#page-134-4) [\(2017\)](#page-134-4) by adding a cocoercive operator to the inclusion [\(6.6\)](#page-59-8).

Proposition 6.10. Let $\tau \in]0, +\infty[$, let $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, and let $C: \mathcal{H} \to \mathcal{H}$ be τ -cocoercive. Suppose that the set Z of solutions to the inclusion

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + Bx + Cx$ (6.33)

is not empty and let Z^* be the set of solutions to the dual problem

find
$$
x^* \in \mathcal{H}
$$
 such that $0 \in -(A + C)^{-1}(-x^*) + B^{-1}x^*$. (6.34)

Let $\gamma \in [0, 2\tau]$, set $\delta = 2 - \gamma/(2\tau)$, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $[0, \delta]$ such that $\sum_{n \in \mathbb{N}} \lambda_n(\delta - \lambda_n) = +\infty$, and let $y_0 \in \mathcal{H}$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n x_n = J_{\gamma B} y_n \\
 x_n^* = \gamma^{-1} (y_n - x_n) \\
 r_n = y_n + \gamma C x_n \\
 z_n = J_{\gamma A} (2x_n - r_n) \\
 y_{n+1} = y_n + \lambda_n (z_n - x_n).\n\end{cases}
$$
\n(6.35)

Then there exists $y \in \mathcal{H}$ such that $y_n \to y$. Now set $x = J_{\gamma} g y$ and $x^* = \gamma g y$. Then the following hold:

- (i) $x_n \to x \in \mathbb{Z}$.
- (ii) $x_n^* \rightharpoonup x^* \in Z^*$.

Proof. Remarkably, we can closely follow the proof of Theorem [6.2.](#page-58-3) The key additional facts established in [Davis and Yin](#page-134-4) [\(2017,](#page-134-4) Proposition 2.1 and Lemma 2.2) are that, for $\alpha = 1/\delta$,

$$
T = J_{\gamma A} \circ (2J_{\gamma B} - \text{Id} - \gamma C \circ J_{\gamma B}) + \text{Id} - J_{\gamma B} \text{ is } \alpha \text{-averaged and } Z = J_{\gamma B}(\text{Fix } T). \tag{6.36}
$$

We write the maximally monotone operator $\mathcal M$ of [\(3.26\)](#page-27-1) as

$$
\mathcal{M} = \left(\mathrm{Id} + \frac{1}{2\alpha} (J_{\gamma A} \circ (2J_{\gamma B} - \mathrm{Id} - \gamma C \circ J_{\gamma B}) - J_{\gamma B}) \right)^{-1} - \mathrm{Id} \tag{6.37}
$$

and, in view of Example [3.16](#page-27-0) and [\(6.36\)](#page-65-0), work with the embedding (H, M, J_{γ}) of [\(6.33\)](#page-65-1). Then $\emptyset \neq Z = J_{\gamma B}(\text{zer } M)$ and $(y_n)_{n \in \mathbb{N}}$ is produced by the proximal point algorithm ($\forall n \in \mathbb{N}$) $y_{n+1} = y_n + \mu_n (J_{\mathcal{M}}y_n - y_n)$, where $\mu_n = 2\alpha \lambda_n \in]0, 2[$. Using Theorem [5.1\(](#page-42-2)[i\)](#page-42-1), we infer that $(y_n)_{n \in \mathbb{N}}$ converges weakly to a point $y \in \text{zer } M$ and that $J_{\mathcal{M}}y_n - y_n \to 0$. Hence, we derive from [\(6.36\)](#page-65-0), [\(6.35\)](#page-65-2) and [\(6.37\)](#page-65-3) that

$$
x = J_{\gamma B} y \in Z \quad \text{and} \quad z_n - x_n = 2\alpha (J_{\mathcal{M}} y_n - y_n) \to 0,\tag{6.38}
$$

and hence that

$$
||Cz_n - Cx_n|| \le \alpha^{-1} ||z_n - x_n|| \to 0.
$$
 (6.39)

[\(i\)](#page-65-4) Set ($\forall n \in \mathbb{N}$) $z_n^* = \gamma^{-1}(2x_n - z_n - r_n) + Cz_n$. In view of [\(6.35\)](#page-65-2) and [\(2.18\)](#page-7-1),

$$
(\forall n \in \mathbb{N}) \quad \begin{cases} (z_n, z_n^*) \in \text{gra}(A + C), \\ (x_n, x_n^*) \in \text{gra } B, \\ z_n^* + x_n^* = \gamma^{-1}(x_n - z_n) + Cz_n - Cx_n. \end{cases} \tag{6.40}
$$

Next, fix $z \in \mathfrak{W}(x_n)_{n \in \mathbb{N}}$, say $x_{k_n} \to z$. Since $y_{k_n} \to y$, it follows from [\(6.38\)](#page-65-5), [\(6.39\)](#page-65-6), [\(6.40\)](#page-66-0) and [\(6.35\)](#page-65-2) that

$$
z_{k_n} \to z
$$
, $z_{k_n}^* \to \gamma^{-1}(z - y)$, $z_n - x_n \to 0$ and $z_n^* + x_n^* \to 0$. (6.41)

By applying Lemma [2.50](#page-23-0) to the maximally monotone operators $A + C$ (see Ex-ample [2.5](#page-12-0) and Lemma [2.27](#page-17-0)[\(ii\)](#page-17-1)) and B , we deduce from (6.40) and (6.41) that $z \in \text{zer}(A + C + B) = Z$,

$$
(z, \gamma^{-1}(z - y)) \in \text{gra}(A + C)
$$
 and $(z, \gamma^{-1}(y - z)) \in \text{gra } B.$ (6.42)

In turn, [\(2.18\)](#page-7-1) asserts that $z = J_{\gamma B}y$, making $x = J_{\gamma B}y$ the unique weak sequential cluster point of $(x_n)_{n \in \mathbb{N}}$ which is bounded since $(y_n)_{n \in \mathbb{N}}$ is. By Lemma [4.1\(](#page-30-3)[ii\)](#page-30-4), $x_n \rightarrow x$.

[\(ii\)](#page-65-7) Since $y_n \to y$ and $x_n \to x$, we have $x_n^* = \gamma^{-1}(y_n - x_n) \to \gamma^{-1}(y - x) = \gamma^*By =$ $x^* \in Z^*$ by [\(6.11\)](#page-59-7). \Box

Remark 6.11. Here are a few comments on Proposition [6.10.](#page-64-4)

- (i) The conclusion of Proposition [6.10](#page-64-4)[\(i\)](#page-65-4) was first established in [Davis and Yin](#page-134-4) [\(2017,](#page-134-4) Theorem 2.1.1(b)) with a different proof. See also [Raguet](#page-141-4) [\(2019\)](#page-141-4) for a discussion and connections with [Raguet](#page-141-5) *et al.* [\(2013\)](#page-141-5).
- (ii) The duality result of Proposition [6.10\(](#page-64-4)[ii\)](#page-65-7) is new.
- (iii) A strongly convergent version of Proposition [6.10](#page-64-4) can be obtained by adapting the proof of Theorem [6.6](#page-61-1) to the presence of C , as was done above.
- (iv) When $C = 0$, Proposition [6.10](#page-64-4) produces the Douglas–Rachford setting of Theorem [6.2.](#page-58-3) When $B = 0$, [\(6.35\)](#page-65-2) yields a special case of the forward– backward method of [Combettes and Yamada](#page-133-6) [\(2015,](#page-133-6) Proposition 4.4(iii)) in which the proximal parameters are all equal to γ .

7. Tseng's forward–backward–forward splitting

7.1. Preview

In Section [5.4.1,](#page-45-4) we have discussed a Euler method for finding a zero of a singlevalued operator $B: H \rightarrow H$ under a cocoercivity condition. Under the more general assumption that B is monotone and β -Lipschitzian, the Euler method is no longer appropriate, and we can use a scheme proposed by [Antipin](#page-126-1) [\(1976\)](#page-126-1) and [Korpelevič](#page-137-4) (1976) that involves a double activation of the operator B. Specifically, in this method, $\gamma \in [0, 1/\beta]$ and $x_0 \in \mathcal{H}$ are fixed and we iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nb_n^* = \gamma Bx_n \\
m_n = x_n - b_n^* \\
m_n^* = Bm_n \\
x_{n+1} = x_n - \gamma m_n^*.\n\end{cases}
$$
\n(7.1)

Clearly, the sequence $(m_n, m_n^*)_{n \in \mathbb{N}}$ lies gra B and it is straightforward to see that, by choosing $(\lambda_n)_{n \in \mathbb{N}}$ suitably in [\(4.32\)](#page-38-0), we obtain [\(7.1\)](#page-67-0). The convergence properties of the Antipin–Korpelevič method can therefore be deduced from the results of Section [4.4](#page-35-1) applied to B .

Tseng's algorithm can be viewed as a generalization of [\(7.1\)](#page-67-0) for the problem of finding a zero of $A + B$, where $A: \mathcal{H} \to 2^{\mathcal{H}}$ is maximally monotone and B is as above. It is called the forward–backward–forward algorithm because it performs a forward step on B , then a backward step on A , and finally another forward step on B. We are going to derive the convergence of Tseng's forward–backward–forward splitting algorithm from the principles of Section [4.4](#page-35-1) and, more precisely, from the warped resolvent algorithm of Section [4.5.](#page-38-1)

7.2. Fejérian algorithm

We cast the forward–backward–forward algorithm as an instance of (4.34) and then prove its weak convergence via Theorem[4.12.](#page-39-9) This result was originally established in [Tseng](#page-143-3) [\(2000,](#page-143-3) Theorem 3.4(b)), where different arguments were used.

Theorem 7.1. Let $\beta \in]0, +\infty[$, let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, let $B: H \to H$ be monotone and β -Lipschitzian, and suppose that $Z = \text{zer}(A+B) \neq \emptyset$. Let $x_0 \in \mathcal{H}$, let $\varepsilon \in [0, 1/(\beta + 1)]$, and let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (1 - \varepsilon)/\beta]$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nb_n^* = \gamma_n B x_n \\
m_n = J_{\gamma_n} A (x_n - b_n^*) \\
x_{n+1} = m_n - \gamma_n B m_n + b_n^*.\n\end{cases}
$$
\n(7.2)

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z.

Proof. Our objective is to apply Theorem [4.12](#page-39-9) with

 $W = A + B$, $C = 0$, and $(\forall n \in \mathbb{N})$ $U_n = \gamma_n^{-1} \text{Id} - B$ and $q_n = w_n$. (7.3)

Since $C = 0$, let us rename $(w_n)_{n \in \mathbb{N}}$ as $(m_n)_{n \in \mathbb{N}}$. Example [2.3](#page-12-2) and Lemma [2.27\(](#page-17-0)[ii\)](#page-17-1) entail that W is maximally monotone. Moreover, a consequence of Lemma [2.48](#page-22-1)[\(i\)](#page-22-2)– [\(ii\)](#page-22-3) is that

($\forall n \in \mathbb{N}$) $\gamma_n U_n$ is ε -strongly monotone and $1/(2 - \varepsilon)$ -cocoercive. (7.4)

Additionally, we derive from [Bùi and Combettes](#page-130-0) [\(2020](#page-130-0)*b*, Proposition 3.9) that

$$
(\forall n \in \mathbb{N})
$$
 ran $U_n \subset \text{ran}(U_n + W + C)$ and $U_n + W + C$ is injective. (7.5)
We also observe that

We also observe that

$$
(\forall n \in \mathbb{N}) \quad J_{W+C}^{U_n} = J_{A+B}^{U_n} = (\gamma_n^{-1} \text{Id} + A) \circ (\gamma_n^{-1} \text{Id} - B) = J_{\gamma_n A} \circ (\text{Id} - \gamma_n B). \tag{7.6}
$$

Hence, the variables of [\(4.34\)](#page-39-0) in this setting become

$$
(\forall n \in \mathbb{N}) \quad \begin{cases} m_n = J_{\gamma_n A}(x_n - \gamma_n B x_n), \\ t_n^* = U_n x_n - U_n m_n, \\ \delta_n = \langle m_n - x_n | U_n m_n - U_n x_n \rangle. \end{cases} \tag{7.7}
$$

Now set

$$
(\forall n \in \mathbb{N}) \quad \lambda_n = \begin{cases} \frac{\gamma_n ||t_n^*||^2}{\delta_n}, & \text{if } \delta_n > 0, \\ \varepsilon, & \text{otherwise.} \end{cases} \tag{7.8}
$$

We derive from [\(7.4\)](#page-67-1) that

$$
(\forall n \in \mathbb{N}) \quad \delta_n = \langle m_n - x_n \mid U_n m_n - U_n x_n \rangle \ge \beta \varepsilon ||m_n - x_n||^2, \tag{7.9}
$$

which implies that

$$
(\forall n \in \mathbb{N}) \quad \delta_n \le 0 \iff m_n = x_n \iff t_n^* = 0. \tag{7.10}
$$

A consequence of [\(7.4\)](#page-67-1) is that, if $\delta_n > 0$,

$$
\frac{\varepsilon}{\gamma_n} \le \frac{\|U_n m_n - U_n x_n\|}{\|m_n - x_n\|} \le \frac{\|U_n m_n - U_n x_n\|^2}{\langle m_n - x_n | U_n m_n - U_n x_n \rangle} \le \frac{2 - \varepsilon}{\gamma_n},\tag{7.11}
$$

and we therefore obtain from [\(7.8\)](#page-68-0) that

$$
\lambda_n = \frac{\gamma_n ||U_n m_n - U_n x_n||^2}{\langle m_n - x_n | U_n m_n - U_n x_n \rangle} \in [\varepsilon, 2 - \varepsilon].
$$
\n(7.12)

Hence, [\(4.34\)](#page-39-0) and [\(7.10\)](#page-68-1) yield

$$
(\forall n \in \mathbb{N}) \quad d_n = \frac{\gamma_n}{\lambda_n} t_n^*.
$$
 (7.13)

Consequently, the sequence $(x_n)_{n \in \mathbb{N}}$ produced by [\(7.2\)](#page-67-2) coincides with that of [\(4.34\)](#page-39-0). We therefore appeal to Theorem [4.12\(](#page-39-9)[ii\)](#page-39-2) to conclude since its condition [\(iib\)](#page-39-4) holds thanks to (7.12) , whereas its condition [\(iid\)](#page-39-6) holds thanks to (7.4) and the fact that $(\gamma_n)_{n \in \mathbb{N}}$ lies in $[\varepsilon, (1 - \varepsilon)/\beta]$. \Box

7.3. Haugazeau-like algorithm

We present a strongly convergent best approximation version of the forward– backward–forward method based on Theorem [4.14.](#page-41-6)

Theorem 7.2. Let $\beta \in]0, +\infty[$, let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, let $B: H \to H$ be monotone and β -Lipschitzian, and suppose that $Z = \text{zer}(A+B) \neq \emptyset$. Let $x_0 \in \mathcal{H}$, let $\varepsilon \in [0, 1/(\beta + 1)]$, and let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (1 - \varepsilon)/\beta]$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nb_n^* = \gamma_n B x_n \\
m_n = J_{\gamma_n} A(x_n - b_n^*) \\
r_n = \frac{1}{2} (x_n + m_n - \gamma_n B m_n + b_n^*) \\
x_{n+1} = Q(x_0, x_n, r_n),\n\end{cases}
$$
\n(7.14)

where Q is defined in Lemma [4.6.](#page-33-0) Then $(x_n)_{n \in \mathbb{N}}$ converges strongly to proj_Z x_0 .

Proof. We prove the claim as an application of Theorem [4.14](#page-41-6) in the setting of [\(7.3\)](#page-67-3). Let us use the same variables as in [\(7.7\)](#page-68-3) and

$$
(\forall n \in \mathbb{N}) \quad \lambda_n = \begin{cases} \frac{\gamma_n ||t_n^*||^2}{2\delta_n}, & \text{if } \delta_n > 0, \\ \varepsilon/2, & \text{otherwise.} \end{cases} \tag{7.15}
$$

Then, using the same arguments as in the proof of Theorem [4.12,](#page-39-9) we see that $(\lambda_n)_{n\in\mathbb{N}}$ lies in [$\varepsilon/2$, 1] and that the sequence $(x_n)_{n\in\mathbb{N}}$ produced by [\(7.14\)](#page-69-0) coincides with that of [\(4.44\)](#page-41-0). Since conditions [\(iib\)](#page-41-3) and [\(iid\)](#page-41-5) in Theorem [4.14\(](#page-41-6)[ii\)](#page-41-2) are fulfilled, we \Box obtain the claim.

7.4. Special cases and variants

7.4.1. The monotone+skew algorithm

The approach presented here was proposed in [Briceño-Arias and Combettes\(2011\)](#page-129-4) to solve the monotone inclusion [\(3.7\)](#page-24-2) and it was the first algorithm to fully split the operators A , B and L . Its methodology conforms to the programme of Framework [1.2:](#page-4-0) we use the embedding of Example [3.20](#page-29-0) to transfer the initial 3-operator problem (3.7) in the primal space H to one involving the Kuhn–Tucker operator $\mathcal{K} = M + S$ of [\(3.10\)](#page-25-6) in the larger primal–dual space $\mathbf{X} = \mathcal{H} \oplus \mathcal{G}$. The algorithmic strategy *per se* is then straightforward: since \vec{M} is maximally monotone and \vec{S} is monotone and Lipschitzian, we can apply Tseng's forward–backward–forward algorithm (Theorem [7.1\)](#page-67-4) in **X** to find a Kuhn–Tucker point and hence a primal–dual solution.

We derive from Theorem [7.1](#page-67-4) the weak convergence of the monotone+skew algorithm of [Briceño-Arias and Combettes](#page-129-4) [\(2011,](#page-129-4) Theorem 3.1(ii)) (we can derive a strongly convergent version from Theorem [7.2](#page-68-4) using the same arguments).

Proposition 7.3. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{G} \to 2^{\mathcal{G}}$ be maximally monotone, and assume that $0 \neq L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$. Suppose that the set Z of solutions to the primal inclusion

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + L^*(B(Lx))$ (7.16)

is not empty and let Z^* be the set of solutions to the dual inclusion

find
$$
y^* \in \mathcal{G}
$$
 such that $0 \in -L(A^{-1}(-L^*y^*)) + B^{-1}y^*$. (7.17)

Let $x_0 \in \mathcal{H}$, let y_0^* $\gamma_0^* \in \mathcal{G}$, let $\varepsilon \in]0, 1/(\Vert L \Vert + 1)[$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (1-\varepsilon)/||L||]$, and set

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\ny_{1,n} = x_n - \gamma_n L^* y_n^* \\
y_{2,n}^* = y_n^* + \gamma_n L x_n \\
m_{1,n} = J_{\gamma_n} A y_{1,n} \\
m_{2,n}^* = J_{\gamma_n} B^{-1} y_{2,n}^* \\
q_{1,n} = m_{1,n} - \gamma_n L^* m_{2,n}^* \\
q_{2,n}^* = m_{2,n}^* + \gamma_n L m_{1,n} \\
x_{n+1} = x_n - y_{1,n} + q_{1,n} \\
y_{n+1}^* = y_n^* - y_{2,n}^* + q_{2,n}^*. \n\end{cases} (7.18)
$$

Then there exist $x \in Z$ and $y^* \in Z^*$ such that $-L^*y^* \in Ax$, $y^* \in B(Lx)$, $x_n \to x$ and $y_n^* \rightharpoonup y^*$.

Proof. Set $X = H \oplus G$, define M and S as in [\(3.9\)](#page-25-7), and set $(\forall n \in \mathbb{N})$ $x_n = (x_n, y_n^*)$, $y_n = (y_{1,n}, y_{2,n}^*)$, $m_n = (m_{1,n}, m_{2,n}^*)$ and $q_n = (q_{1,n}, q_{2,n}^*)$. Then, in view of Example 2.37 , (7.18) becomes

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\ny_n = x_n - \gamma_n S x_n \\
m_n = J_{\gamma_n} M y_n \\
q_n = m_n - \gamma_n S m_n \\
x_{n+1} = x_n - y_n + q_n,\n\end{cases}
$$
\n(7.19)

which we rewrite as an instance of (7.2) , namely,

Ī

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n\mathbf{b}_n^* = \gamma_n S \mathbf{x}_n \\
\mathbf{m}_n = J_{\gamma_n} M(\mathbf{x}_n - \mathbf{b}_n^*) \\
\mathbf{x}_{n+1} = \mathbf{m}_n - \gamma_n S \mathbf{m}_n + \mathbf{b}_n^*. \n\end{cases}
$$
\n(7.20)

It then follows from Theorem [7.1](#page-67-4) and Lemma [3.8](#page-24-1) that $(x_n)_{n\in\mathbb{N}}$ converges weakly to a point in $zer(M + S) \subset Z \times Z^*$, as claimed. \Box

Remark 7.4. The methodology of Theorem [7.1](#page-67-4) is to find a Kuhn–Tucker point, i.e. a zero of $M + S$. As noted in [Briceño-Arias and Combettes](#page-129-4) [\(2011,](#page-129-4) Remark 2.9), this can also be achieved by using the Douglas–Rachford algorithm [\(6.8\)](#page-59-0) which, upon setting $U = (\text{Id} + \gamma^2 L^* \circ L)^{-1}$ and $V = (\text{Id} + \gamma^2 L \circ L^*)^{-1}$, and taking $\gamma \in]0, +\infty[$ and a sequence $(\lambda_n)_{n \in \mathbb{N}}$ in $]0, 2[$ such that $\sum_{n \in \mathbb{N}} \lambda_n (2 - \lambda_n) = +\infty$,

assumes the form

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nx_n = U(y_{1,n} - \gamma L^* y_{2,n}^*) \\
y_n^* = V(y_{2,n}^* + \gamma L y_{1,n}) \\
y_{1,n+1} = y_{1,n} + \lambda_n (J_{\gamma A}(2x_n - y_{1,n}) - x_n) \\
y_{2,n+1}^* = y_{2,n}^* + \lambda_n (J_{\gamma B^{-1}}(2y_n^* - y_{2,n}^*) - y_n^*).\n\end{cases}
$$
\n(7.21)

Weak convergence of $(x_n, y_n^*)_{n \in \mathbb{N}}$ to a point in $Z \times Z^*$ follows from Theorem [6.2\(](#page-58-3)[i\)](#page-59-3). The numerical effectiveness of [\(7.21\)](#page-71-0) depends on the ease of implementation of the operators U and V . This approach was rediscovered in [O'Connor and Vandenberghe](#page-140-2) [\(2014\)](#page-140-2) in an image restoration application.

7.4.2. A Lagrangian approach to composite minimization

We revisit the setting of Problem [3.9,](#page-25-3) which was identified as an instance of Problem [3.7](#page-24-0) and can therefore be solved using [\(7.18\)](#page-70-0) with $A = \partial f$ and $B = \partial g$. Following [Combettes](#page-132-0) [\(2018,](#page-132-0) Section 4.5), we explore a different route which amounts to employing the embedding (X, S_F, \mathcal{T}) , where $X = \mathcal{H} \oplus \mathcal{G} \oplus \mathcal{G}$,

$$
\mathcal{S}_F: \quad \mathbf{X} \quad \to \quad 2^{\mathbf{X}} \quad (x, y, v^*) \quad \mapsto \quad (\partial f(x) + L^* v^*) \times (\partial g(y) - v^*) \times \{-Lx + y\} \tag{7.22}
$$

is the saddle operator of [\(3.24\)](#page-27-3), and $\mathcal{T}: \mathbf{X} \to \mathcal{H}: (x, y, v^*) \mapsto x$. Let us write $S_F = M + S$, where

$$
\begin{cases}\nM: (x, y, v^*) \mapsto \partial f(x) \times \partial g(y) \times \{0\}, \\
S: (x, y, v^*) \mapsto (L^*v^*, -v^*, -Lx + y).\n\end{cases}
$$
\n(7.23)

Then $||S|| = \sqrt{1 + ||L||^2}$ and $(\forall n \in \mathbb{N}) J_{\gamma_n} M = \text{prox}_{\gamma_n} f \times \text{prox}_{\gamma_n} g \times \text{Id}$. Hence, applying Theorem [7.1](#page-67-4) to this decomposition in **X**, we obtain the following realization of Framework [1.2.](#page-4-0)

Proposition 7.5. Let $f \in \Gamma_0(\mathcal{H})$, $g \in \Gamma_0(\mathcal{G})$ and $L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$ be such that $0 \in \text{sri}(L(\text{dom } f) - \text{dom } g)$. Suppose that the primal problem

$$
\underset{x \in \mathcal{H}}{\text{minimize}} \quad f(x) + g(Lx) \tag{7.24}
$$

admits solutions and consider the dual problem

minimize
$$
f^*(-L^*v^*) + g^*(v^*).
$$
 (7.25)

Let $(x_0, y_0, v_0^*) \in \mathcal{H} \oplus \mathcal{G} \oplus \mathcal{G}$, let $\varepsilon \in]0, 1/(1 + \sqrt{1 + ||L||^2})[$, and let $(\gamma_n)_{n \in \mathbb{N}}$ be a
sequence in $[\varepsilon, (1 - \varepsilon)/\sqrt{1 + ||L||^2}]$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nr_n = \gamma_n (Lx_n - y_n) \\
m_{1,n} = \text{prox}_{\gamma_n f} (x_n - \gamma_n L^* v_n^*) \\
m_{2,n} = \text{prox}_{\gamma_n g} (y_n + \gamma_n v_n^*) \\
x_{n+1} = m_{1,n} - \gamma_n L^* r_n \\
y_{n+1} = m_{2,n} + \gamma_n r_n \\
v_{n+1}^* = v_n^* + \gamma_n (Lm_{1,n} - m_{2,n}).\n\end{cases}
$$
\n(7.26)

Then $(x_n)_{n \in \mathbb{N}}$ and $(v_n^*)_{n \in \mathbb{N}}$ converge weakly to solutions to [\(7.24\)](#page-71-0) and [\(7.25\)](#page-71-1), respectively.

Remark 7.6. Let $(\mu_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (1 - \varepsilon) \min\{1, 1/\Vert L \Vert\}/2]$. Algorithm [\(7.26\)](#page-72-0) bears a certain resemblance with the iterative scheme

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n p_n = v_n^* + \mu_n (Lx_n - y_n) \\
 x_{n+1} = \text{prox}_{\mu_n f} (x_n - \mu_n L^* p_n) \\
 y_{n+1} = \text{prox}_{\mu_n g} (y_n + \mu_n p_n) \\
 v_{n+1}^* = v_n^* + \mu_n (Lx_{n+1} - y_{n+1})\n\end{cases}
$$
\n(7.27)

proposed in [Chen and Teboulle](#page-131-0) [\(1994\)](#page-131-0) to solve [\(7.24\)](#page-71-0)–[\(7.25\)](#page-71-1) in a finite-dimensional setting.

Remark 7.7. In the finite-dimensional context of [Eckstein](#page-134-0) [\(1994\)](#page-134-0), the saddle operator [\(7.22\)](#page-71-2) was split as $S_F = M_1 + M_2$, where

$$
\begin{cases} M_1: (x, y, v^*) \mapsto (\partial f(x) + L^* v^*) \times \{0\} \times \{-Lx\}, \\ M_2: (x, y, v^*) \mapsto \{0\} \times (\partial g(y) - v^*) \times \{y\}. \end{cases}
$$
(7.28)

Given $\gamma \in]0, +\infty[$, $\mu_1 \in \mathbb{R}, \mu_2 \in \mathbb{R}$ and $(x_0, y_0, v_0^*) \in \mathcal{H} \oplus \mathcal{G} \oplus \mathcal{G}$, applying the Douglas–Rachford algorithm [\(6.8\)](#page-59-0) to find a zero of $M_1 + M_2$ leads to the algorithm [\(Eckstein](#page-134-0) [1994\)](#page-134-0)

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nx_{n+1} \in \text{Argmin} \\
x_{n+1} = \text{Argmin} \\
y_{n+1} = \underset{y \in \mathcal{G}}{\text{argmin}} \\
\begin{pmatrix}\ng(y) - \langle y | v_n^* \rangle + \frac{1}{2\gamma} ||Lx - y_n||^2 + \frac{\gamma \mu_1^2}{2} ||x - x_n||^2 \\
y_{n+1} = \underset{y \in \mathcal{G}}{\text{argmin}} \\
v_{n+1}^* = v_n^* + \gamma^{-1} (Lx_{n+1} - y_{n+1}).\n\end{pmatrix}\n\end{cases}
$$
\n(7.29)

When $\mu_1 = \mu_2 = 0$, we recover the alternating direction method of multipliers (ADMM) discussed in Remark 6.9 [\(ii\)](#page-62-1). Just like ADMM, (7.29) necessitates a potentially complex minimization involving f and L jointly to construct x_{n+1} . By contrast, (7.26) achieves full splitting of f, g and L.

Remark 7.8. In view of Example [3.23,](#page-30-0) the above saddle operator formalism can be extended to the more general primal–dual inclusion pair of Problem [3.7.](#page-24-0) As in Proposition [7.5,](#page-71-3) a zero (x, y, v^*) of the saddle operator S of [\(3.25\)](#page-27-0) can be constructed by executing [\(7.26\)](#page-72-0), where $prox_{\gamma_n} f$ is replaced with $J_{\gamma_n} A$ and $prox_{\gamma_n} g$ with J_{γ_n} . In this setting, the weak limits x and v^* solve, respectively, the primal inclusion [\(3.7\)](#page-24-1) and the dual inclusion [\(3.8\)](#page-24-2).

7.4.3. Mixtures of composite, Lipschitzian and parallel-sum operators

The Kuhn–Tucker operator of Lemma [3.8](#page-24-3) employed in Section [7.4.1](#page-69-0) can be expressed in block format as

$$
\mathcal{K} = \mathbf{M} + \mathbf{S} = \underbrace{\begin{bmatrix} A & 0 \\ 0 & B^{-1} \end{bmatrix}}_{\text{monotone}} + \underbrace{\begin{bmatrix} 0 & L^* \\ -L & 0 \end{bmatrix}}_{\text{skew}}.
$$
 (7.30)

A Kuhn–Tucker point was obtained in Proposition [7.3](#page-69-1) by applying the forward– backward–forward algorithm (7.2) to \vec{M} and \vec{S} . In doing so, we did not exploit the linearity and skewness of S , but just the fact that it is monotone and Lipschitzian. Let us observe that, if we fill the diagonal of S with monotone Lipschitzian operators $Q\colon\mathcal{H}\to\mathcal{H}$ and $D^{-1}\colon\mathcal{G}\to\mathcal{G},$ we obtain a new monotone and Lipschitzian operator $Q: X \rightarrow X$. In lieu of [\(7.30\)](#page-73-0), we then consider the decomposition

$$
\mathcal{K} = \mathbf{M} + \mathbf{Q} = \underbrace{\begin{bmatrix} A & 0 \\ 0 & B^{-1} \end{bmatrix}}_{\text{monotone}} + \underbrace{\begin{bmatrix} Q & L^* \\ -L & D^{-1} \end{bmatrix}}_{\text{monotone and Lipschitzian}}.
$$
\n
$$
(7.31)
$$

monotone and Lipschitzian

Using [\(2.62\)](#page-17-0), we write

$$
\mathcal{K} = \begin{bmatrix} A + Q & L^* \\ -L & (B \Box D)^{-1} \end{bmatrix} \tag{7.32}
$$

and interpret it as a variant of the Kuhn–Tucker operator [\(3.10\)](#page-25-0) associated with Problem [3.7](#page-24-0) in which A is replaced with $A + Q$ and B with $B \Box D$. In other words, the primal inclusion is to

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + L^*((B \square D)(Lx)) + Qx$ (7.33)

and the dual inclusion is to

find
$$
y^* \in \mathcal{G}
$$
 such that $0 \in -L((A + Q)^{-1}(-L^*y^*)) + B^{-1}y^* + D^{-1}y^*$ (7.34)

or, equivalently,

find
$$
y^* \in \mathcal{G}
$$
 such that $(\exists x \in \mathcal{H})$
$$
\begin{cases} -L^* y^* \in Ax + Qx, \\ Lx \in B^{-1} y^* + D^{-1} y^*. \end{cases}
$$
 (7.35)

As in Lemma [3.8,](#page-24-3) for every $(x, y^*) \in \mathbf{X}$,

$$
(x, y^*) \in \text{zer } \mathcal{K} \quad \Rightarrow \quad \begin{cases} x \text{ solves (7.33)}, \\ y^* \text{ solves (7.35)}, \end{cases} \tag{7.36}
$$

and we therefore recover the embedding principle of Framework [1.2.](#page-4-0)

Example 7.9. In the above setting, set $X = H \oplus G$, let K be the Kuhn–Tucker operator of [\(7.32\)](#page-73-3), and let $\mathcal{T} \colon \mathbf{X} \to \mathcal{H} \colon (x, y^*) \mapsto x$. Then $(\mathbf{X}, \mathcal{K}, \mathcal{T})$ is an embedding of [\(7.33\)](#page-73-1).

The primal–dual inclusion problem [\(7.33\)](#page-73-1)–[\(7.34\)](#page-73-4) was first studied in [Combettes](#page-133-0) [and Pesquet](#page-133-0) [\(2012\)](#page-133-0), where it was solved via Tseng's forward–backward–forward algorithm. Here is Theorem $3.1(ii)(c)$ –(d) of [Combettes and Pesquet](#page-133-0) [\(2012\)](#page-133-0), which describes this approach when the operators L , B and D above are deployed in a product space $\mathcal{G} = \mathcal{G}_1 \oplus \cdots \oplus \mathcal{G}_p$ in the spirit of Problem [3.11;](#page-26-0) further analysis of the asymptotic behaviour of the method in special cases can be found in [Boţ and](#page-129-0) [Hendrich](#page-129-0) [\(2014\)](#page-129-0).

Proposition 7.10. Let $0 < p \in \mathbb{N}$, let $\mu \in]0, +\infty[$, let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, let $Q: \mathcal{H} \to \mathcal{H}$ be monotone and μ -Lipschitzian. For every $k \in$ $\{1,\ldots,p\}$, let $v_k \in]0,+\infty[$, let \mathcal{G}_k be a real Hilbert space, let $B_k: \mathcal{G}_k \to 2^{\mathcal{G}_k}$ be maximally monotone, let $D_k: \mathcal{G}_k \to 2^{\mathcal{G}_k}$ be maximally monotone and such that D_k^{-1} : $\mathcal{G}_k \to \mathcal{G}_k$ is v_k -Lipschitzian, and assume that $0 \neq L_k \in \mathcal{B}(\mathcal{H}, \mathcal{G}_k)$. Suppose that the set Z of solutions to the primal inclusion

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + \sum_{k=1}^{p} L_k^*((B_k \square D_k)(L_k x)) + Qx$ (7.37)

is not empty and let Z^* be the set of solutions to the dual inclusion

find
$$
y_1^* \in G_1, ..., y_p^* \in G_p
$$
 such that
\n
$$
(\exists x \in \mathcal{H}) \begin{cases}\n-\sum_{k=1}^p L_k^* y_k^* \in Ax + Qx, \\
(\forall k \in \{1, ..., p\}) \ L_k x \in B_k^{-1} y_k^* + D_k^{-1} y_k^*.\n\end{cases}
$$
\n(7.38)

Set

$$
\beta = \max\{\mu, \nu_1, \dots, \nu_p\} + \sqrt{\sum_{k=1}^p \|L_k\|^2},\tag{7.39}
$$

let $x_0 \in \mathcal{H}$, let $(y_{1,0}^*, \ldots, y_{p,0}^*) \in \mathcal{G}_1 \oplus \cdots \oplus \mathcal{G}_p$, let $\varepsilon \in [0, 1/(\beta+1)]$, and let

 $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (1 - \varepsilon)/\beta]$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\ny_{1,n} = x_n - \gamma_n (Qx_n + \sum_{k=1}^p L_k^* y_{k,n}^*) \\
m_{1,n} = J_{\gamma_n A} y_{1,n} \\
\text{for } k = 1, ..., p \\
y_{2,k,n}^* = y_{k,n}^* + \gamma_n (L_k x_n - D_k^{-1} y_{k,n}^*) \\
m_{2,k,n}^* = J_{\gamma_n B_k^{-1}} y_{2,k,n}^* \\
q_{2,k,n}^* = m_{2,k,n}^* + \gamma_n (L_k m_{1,n} - D_k^{-1} m_{2,k,n}^*) \\
y_{k,n+1}^* = y_{k,n}^* - y_{2,k,n}^* + q_{2,k,n}^* \\
q_{1,n} = m_{1,n} - \gamma_n (Qm_{1,n} + \sum_{k=1}^p L_k^* m_{2,k,n}^*) \\
x_{n+1} = x_n - y_{1,n} + q_{1,n}.\n\end{cases} (7.40)
$$

Then there exist $x \in Z$ and (y_1^*) $\chi_1^*, \ldots, \chi_p^*$ $\in Z^*$ such that $x_n \to x$, and, for every $k \in \{1, ..., p\}, y_{k,n}^* \to y_k^*.$

Proof. The duality between [\(7.37\)](#page-74-0) and [\(7.38\)](#page-74-1) follows as in Problem [3.11,](#page-26-0) by replacing A with $A + Q$ and $(B_k^{-1})_{1 \le k \le p}$ with $(B_k^{-1} + D_k^{-1})_{1 \le k \le p}$. Now set

$$
\begin{cases}\n\mathcal{G} = \mathcal{G}_1 \oplus \cdots \oplus \mathcal{G}_p, \\
B: \mathcal{G} \to 2^{\mathcal{G}}: (y_1, \ldots, y_p) \mapsto B_1 y_1 \times \cdots \times B_p y_p, \\
D: \mathcal{G} \to 2^{\mathcal{G}}: (y_1, \ldots, y_p) \mapsto D_1 y_1 \times \cdots \times D_p y_p, \\
L: \mathcal{H} \to \mathcal{G}: x \mapsto (L_1 x, \ldots, L_p x),\n\end{cases} \tag{7.41}
$$

define M and Q as in [\(7.31\)](#page-73-5), and set

$$
(\forall n \in \mathbb{N}) \quad \begin{cases} x_n = (x_n, y_{1,n}^*, \dots, y_{p,n}^*), \\ \mathbf{m}_n = (m_{1,n}, m_{2,1,n}^*, \dots, m_{2,p,n}^*). \end{cases} \tag{7.42}
$$

Then M is maximally monotone and Q is monotone and β -Lipschitzian [\(Combettes](#page-133-0) [and Pesquet](#page-133-0) [2012,](#page-133-0) equation (3.11)) and, following the same steps as in the proof of Proposition [7.3,](#page-69-1) we rewrite [\(7.40\)](#page-75-0) as

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n\mathbf{b}_n^* = \gamma_n \mathbf{Q} x_n \\
\mathbf{m}_n = J_{\gamma_n} M(x_n - \mathbf{b}_n^*) \\
x_{n+1} = \mathbf{m}_n - \gamma_n \mathbf{Q} \mathbf{m}_n + \mathbf{b}_n^*,\n\end{cases}
$$
\n(7.43)

and conclude by invoking Theorem [7.1](#page-67-1) and [\(7.36\)](#page-74-2).

Remark 7.11. In [\(7.37\)](#page-74-0), suppose that $p = 1$, $\mathcal{G}_1 = \mathcal{H}$, $L_1 = \text{Id}$, $B_1 = B$, $D_1 =$ ${0}^{-1}$ and zer($A + B + Q$) $\neq \emptyset$. Let $x_0 \in \mathcal{H}$, let y_0^* $e^* \in \mathcal{H}$, let $\varepsilon \in]0, 1/(\mu + 2)[$, and let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (1 - \varepsilon)/(\mu + 1)]$. Then we deduce from

$$
\qquad \qquad \Box
$$

Proposition [7.10](#page-74-3) that the sequence $(x_n)_{n \in \mathbb{N}}$ generated by the iterations

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\ny_n = x_n - \gamma_n(Qx_n + y_n^*) \\
p_n = J_{\gamma_n} \Delta y_n \\
q_n^* = J_{\gamma_n} B^{-1}(y_n^* + \gamma_n x_n) \\
x_{n+1} = x_n - y_n + p_n - \gamma_n(Qp_n + q_n^*) \\
y_{n+1}^* = q_n^* + \gamma_n(p_n - x_n).\n\end{cases}
$$
\n(7.44)

converges weakly to a zero of $A + B + Q$. An alternative method to solve this inclusion is proposed in Ryu and V \tilde{u} [\(2020\)](#page-142-0), with constant proximal parameters $(\gamma_n)_{n \in \mathbb{N}}$ and the feature that it coincides with the unrelaxed version of the Douglas– Rachford algorithm when $Q = 0$ (in the spirit of the method of Section [6.4.3](#page-64-0) where Q is cocoercive).

Example 7.12. In Proposition [7.10,](#page-74-3) make the additional assumptions that $Q = 0$ and, for every $k \in \{1, ..., p\}$, $\mathcal{G}_k = \mathcal{H}$, $L_k = \text{Id}$, and D_k^{-1} is strictly monotone. Then [\(7.37\)](#page-74-0) collapses to

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + \sum_{k=1}^{p} (B_k \square D_k)(x)$. (7.45)

It is shown in [Combettes](#page-132-0) [\(2013](#page-132-0)*b*, Proposition 4.2) that [\(7.45\)](#page-76-0) is an exact relaxation of the (possibly inconsistent) instance of the problem

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax$ and $(\forall k \in \{1, ..., p\})$ $0 \in B_kx$ (7.46)

in the sense that the solutions to (7.45) are the same as the solutions to (7.46) when the latter happen to exist.

The specialization of Proposition [7.10](#page-74-3) to minimization is as follows. It features the ability to split infimal convolutions (see [\(2.7\)](#page-6-0)) together with linearly composed functions.

Example 7.13 [\(Combettes and Pesquet](#page-133-0) [2012\)](#page-133-0). Let $0 < p \in \mathbb{N}$, let $\mu \in [0, +\infty)$, let $f \in \Gamma_0(\mathcal{H})$, and let $h: \mathcal{H} \to \mathbb{R}$ be convex, differentiable, and such that ∇h is μ -Lipschitzian. For every $k \in \{1, ..., p\}$, let $v_k \in [0, +\infty[$, let \mathcal{G}_k be a real Hilbert space, let $g_k \in \Gamma_0(\mathcal{G}_k)$, let $\ell_k \in \Gamma_0(\mathcal{G}_k)$ be $1/\nu_k$ -strongly convex, and suppose that $0 \neq L_k \in \mathcal{B}(\mathcal{H}, \mathcal{G}_k)$. Let Z be the set of solutions to the primal problem

$$
\underset{x \in \mathcal{H}}{\text{minimize}} \quad f(x) + \sum_{k=1}^{p} (g_k \Box \ell_k)(L_k x) + h(x),\tag{7.47}
$$

let Z^* be the set of solutions to the dual problem

$$
\underset{y_1^* \in \mathcal{G}_1, \dots, y_p^* \in \mathcal{G}_p}{\text{minimize}} \quad (f^* \Box h^*) \left(-\sum_{k=1}^p L_k^* y_k^* \right) + \sum_{k=1}^p (g_k^*(y_k^*) + \ell_k^*(y_k^*)),\tag{7.48}
$$

and suppose that

$$
\operatorname{zer}\left(\partial f + \sum_{k=1}^p L_k^* \circ (\partial g_k \Box \partial \ell_k) \circ L_k + \nabla h\right) \neq \emptyset. \tag{7.49}
$$

Set

$$
\beta = \max\{\mu, \nu_1, \dots, \nu_p\} + \sqrt{\sum_{k=1}^p \|L_k\|^2},\tag{7.50}
$$

let $x_0 \in \mathcal{H}$, let $(y_{1,0}^*, \ldots, y_{p,0}^*) \in \mathcal{G}_1 \oplus \cdots \oplus \mathcal{G}_p$, let $\varepsilon \in [0, 1/(\beta+1)]$, and let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (1 - \varepsilon)/\beta]$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\ny_{1,n} = x_n - \gamma_n (\nabla h(x_n) + \sum_{k=1}^p L_k^* y_{k,n}^*) \\
m_{1,n} = \text{prox}_{\gamma_n f} y_{1,n} \\
\text{for } k = 1, ..., p \\
y_{2,k,n}^* = y_{k,n}^* + \gamma_n (L_k x_n - \nabla \ell_k^* (y_{k,n}^*)) \\
m_{2,k,n}^* = \text{prox}_{\gamma_n g_k^*} y_{2,k,n}^* \\
q_{2,k,n}^* = m_{2,k,n}^* + \gamma_n (L_k m_{1,n} - \nabla \ell_k^* (m_{2,k,n}^*)) \\
y_{k,n+1}^* = y_{k,n}^* - y_{2,k,n}^* + q_{2,k,n}^* \\
q_{1,n} = m_{1,n} - \gamma_n (\nabla h(m_{1,n}) + \sum_{k=1}^p L_k^* m_{2,k,n}^*) \\
x_{n+1} = x_n - y_{1,n} + q_{1,n}.\n\end{cases} (7.51)
$$

Then there exist $x \in Z$ and (y_1^*) $\chi_1^*, \ldots, \chi_p^*$ $\in Z^*$ such that $x_n \to x$, and, for every $k \in \{1, ..., p\}, y_{k,n}^* \to y_k^*.$

Remark 7.14. Conditions under which [\(7.49\)](#page-77-0) holds are provided in [Combettes](#page-133-0) [and Pesquet](#page-133-0) [\(2012,](#page-133-0) Proposition 4.3).

8. Forward–backward splitting

8.1. Preview

The forward–backward splitting method is a basic algorithm for solving Problem[3.1](#page-23-0) when *B* is cocoercive. At iteration *n*, given a step size $\gamma_n \in [0, +\infty[$, a discrete dynamics associated with the Cauchy problem [\(5.1\)](#page-42-0) with $M = A + B$ is

$$
\frac{x_n - x_{n+1}}{\gamma_n} \in Ax_{n+1} + Bx_n. \tag{8.1}
$$

It amounts to performing a forward Euler step relative to the operator B and a backward Euler step relative to the operator A . In view of (2.18) , this means that $x_{n+1} = J_{\gamma_n} A(x_n - \gamma_n B x_n)$. This iteration scheme goes back to the gradientprojection method [\(Goldstein](#page-136-0) [1964,](#page-136-0) [Levitin and Polyak](#page-138-0) [1966\)](#page-138-0) for the constrained minimization of a smooth function (see Example [8.7](#page-82-0) below) and its extension to variational inequalities (Bakušinskiı̆ and Polyak [1974,](#page-127-0) [Mercier](#page-139-0) [1979\)](#page-139-0).

8.2. Fejérian algorithm

We establish a new, geometric proof of the convergence of a relaxed primal–dual version of the forward–backward algorithm found in [Combettes and Yamada](#page-133-1) [\(2015,](#page-133-1) Proposition 4.4(iii)) for the primal result and in [Bauschke and Combettes](#page-127-1) [\(2017,](#page-127-1) Theorem 26.14(ii)) for the dual result, where the proximal parameters $(\gamma_n)_{n \in \mathbb{N}}$ are constant. Related primal results and special cases can be found in [Gabay](#page-135-0) [\(1983\)](#page-135-0), [Lemaire](#page-138-1) [\(1996,](#page-138-1) [1997\)](#page-138-2), [Mercier](#page-139-1) [\(1980\)](#page-139-1) and [Tseng](#page-143-0) [\(1991\)](#page-143-0). The importance of cocoercivity in establishing weak convergence was first identified by [Mercier](#page-139-0) [\(1979\)](#page-139-0) in the context of variational inequalities and, more generally, in [Mercier](#page-139-1) [\(1980\)](#page-139-1).

Theorem 8.1. Let $\alpha \in]0, +\infty[$, let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, and let $B: \mathcal{H} \to \mathcal{H}$ be α -cocoercive. Let $\varepsilon \in [0, \alpha/(\alpha+1)]$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (2-\varepsilon)\alpha]$, and let

$$
(\forall n \in \mathbb{N}) \quad \varepsilon \le \mu_n \le (1 - \varepsilon) \frac{4\alpha - \gamma_n}{2\alpha}.\tag{8.2}
$$

Suppose that the set Z of solutions to the problem

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + Bx$ (8.3)

is not empty and let Z^* be the set of solutions to the dual problem

find
$$
x^* \in \mathcal{H}
$$
 such that $0 \in -A^{-1}(-x^*) + B^{-1}x^*$. (8.4)

Let $x_0 \in \mathcal{H}$ and iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nb_n^* = \gamma_n B x_n \\
w_n = J_{\gamma_n A}(x_n - b_n^*) \\
x_{n+1} = x_n + \mu_n (w_n - x_n).\n\end{cases}
$$
\n(8.5)

Then the following hold:

- (i) $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z.
- (ii) Z^* contains a single point \overline{x}^* and $(\forall z \in Z)$ $Bz = \overline{x}^*$.
- (iii) $(Bx_n)_{n \in \mathbb{N}}$ converges strongly to \overline{x}^* .

Proof. The proof hinges on an application of Theorem [4.12](#page-39-0) with

 $W = A$, $C = B$ and $(\forall n \in \mathbb{N})$ $U_n = \gamma_n^{-1} \text{Id} - B$ and $q_n = x_n$. (8.6)

In this setting

$$
(\forall n \in \mathbb{N}) \quad J_{W+C}^{U_n} = J_{A+B}^{U_n} = (\gamma_n^{-1} \text{Id} + A) \circ (\gamma_n^{-1} \text{Id} - B) = J_{\gamma_n A} \circ (\text{Id} - \gamma_n B) \tag{8.7}
$$

and the variables of [\(4.34\)](#page-39-1) become

$$
(\forall n \in \mathbb{N}) \quad \begin{cases} w_n = J_{\gamma_n A}(x_n - \gamma_n B x_n), \\ t_n^* = \frac{x_n - w_n}{\gamma_n}, \\ \delta_n = \left(\frac{1}{\gamma_n} - \frac{1}{4\alpha}\right) ||w_n - x_n||^2. \end{cases} \tag{8.8}
$$

Furthermore, we derive from [Bùi and Combettes\(2020](#page-130-0)*b*, Proposition 3.9) that [\(7.5\)](#page-68-0) holds. Now set

$$
(\forall n \in \mathbb{N}) \quad \lambda_n = \frac{4\alpha\mu_n}{4\alpha - \gamma_n}.\tag{8.9}
$$

Then [\(8.2\)](#page-78-0) yields

$$
(\forall n \in \mathbb{N}) \quad \varepsilon \le \frac{4\alpha\varepsilon}{4\alpha - \varepsilon} \le \lambda_n \le \frac{4\alpha(1 - \varepsilon)(4\alpha - \gamma_n)}{(4\alpha - \gamma_n)2\alpha} \le 2 - \varepsilon. \tag{8.10}
$$

We also deduce from [\(8.8\)](#page-79-0) that

$$
(\forall n \in \mathbb{N}) \quad \delta_n \le 0 \iff w_n = x_n \iff t_n^* = 0. \tag{8.11}
$$

Hence, [\(4.34\)](#page-39-1) yields

$$
(\forall n \in \mathbb{N}) \quad d_n = \frac{\mu_n}{\lambda_n} (x_n - w_n). \tag{8.12}
$$

Altogether, we arrive at the conclusion that the sequence $(x_n)_{n\in\mathbb{N}}$ produced by [\(8.5\)](#page-78-1) coincides with that of [\(4.34\)](#page-39-1). Hence, by Theorem [4.12](#page-39-0)[\(i\)](#page-39-2) and [\(8.10\)](#page-79-1),

$$
\sum_{n \in \mathbb{N}} ||d_n||^2 < +\infty. \tag{8.13}
$$

In turn, upon invoking [\(8.12\)](#page-79-2), we obtain

$$
w_n - x_n \to 0. \tag{8.14}
$$

[\(i\)](#page-78-2) In view of (8.10) , condition [\(iib\)](#page-39-3) in Theorem $4.12(i)$ $4.12(i)$ is fulfilled. On the other hand, since Lemma [2.48\(](#page-22-0)[iii\)](#page-22-1) asserts that the operators $(\gamma_n U_n)_{n \in \mathbb{N}}$ are nonexpansive, [\(8.14\)](#page-79-3) implies that $||U_n w_n - U_n x_n|| \le ||w_n - x_n||/ \varepsilon \to 0$, so that condition [\(iic\)](#page-39-5) is also fulfilled. Thus, the assertion follows from Theorem [4.12\(](#page-39-0)[ii\)](#page-39-4).

[\(ii\)](#page-78-3) The strong monotonicity of B^{-1} implies that of $-A^{-1} \circ (-Id) + B^{-1}$. Hence, Corollary 23.37(ii) of [Bauschke and Combettes](#page-127-1) [\(2017\)](#page-127-1) asserts that [\(8.4\)](#page-78-4) admits a unique solution \bar{x}^* . Now let $z \in Z$. Then $-Bz \in Az$ and therefore $-z \in -A^{-1}(-Bz)$. Thus, $0 = -z + z \in -A^{-1}(-Bz) + B^{-1}(Bz)$, i.e. $Bz \in Z^* = {\overline{x}}^*$.

[\(iii\)](#page-78-5) It follows from [\(i\)](#page-78-2) and [\(8.14\)](#page-79-3) that $(x_n)_{n\in\mathbb{N}}$ and $(w_n)_{n\in\mathbb{N}}$ are bounded. Now let $z \in Z$. We retrieve from [\(4.27\)](#page-36-0) that

$$
(\forall n \in \mathbb{N}) \quad \langle z - w_n \mid t_n^* \rangle \le \langle x_n - w_n \mid Bx_n - Bz \rangle - \alpha ||Bx_n - Bz||^2. \tag{8.15}
$$

Hence, the Cauchy–Schwarz inequality, [\(2.32\)](#page-8-0), [\(8.8\)](#page-79-0) and [\(8.14\)](#page-79-3) imply that

$$
\alpha ||Bx_n - Bz||^2 \le ||w_n - x_n|| ||Bx_n - Bz|| + ||w_n - z|| ||t_n^*||
$$

\n
$$
\le \frac{1}{\alpha} ||w_n - x_n|| ||x_n - z|| + \frac{1}{\gamma_n} ||w_n - z|| ||w_n - x_n||
$$

\n
$$
\to 0.
$$
\n(8.16)
\n
$$
\alpha |(ii) \, Bx_n \to Bz = \overline{x}^*.
$$

In view of [\(ii\)](#page-78-3), $Bx_n \to Bz = \overline{x}^*$.

The following examples address Example [3.2](#page-23-1) and Example [3.3,](#page-24-4) respectively.

Example 8.2. Let $\alpha \in [0, +\infty)$, let $f \in \Gamma_0(\mathcal{H})$, let $B: \mathcal{H} \to \mathcal{H}$ be α -cocoercive, suppose that the set Z of solutions to the variational inequality

find $x \in \mathcal{H}$ such that $(\forall y \in \mathcal{H}) \langle x - y | Bx \rangle + f(x) \leq f(y)$ (8.17)

is not empty, and let Z^* be the set of solutions to the dual problem

find
$$
x^* \in \mathcal{H}
$$
 such that $0 \in -\partial f^*(-x^*) + B^{-1}x^*$. (8.18)

Let $x_0 \in \mathcal{H}$, let $\varepsilon \in [0, \alpha/(\alpha+1)]$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (2-\varepsilon)\alpha]$, and suppose that $(\mu_n)_{n \in \mathbb{N}}$ satisfies [\(8.2\)](#page-78-0). Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nb_n^* = \gamma_n B x_n \\
w_n = \text{prox}_{\gamma_n f} (x_n - b_n^*) \\
x_{n+1} = x_n + \mu_n (w_n - x_n).\n\end{cases}
$$
\n(8.19)

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z and $(Bx_n)_{n \in \mathbb{N}}$ converges strongly to the unique point in Z^* .

Proof. Use Example [2.12](#page-13-0) and Example [2.35](#page-20-0) and set $A = \partial f$ in Theorem [8.1.](#page-78-6) \Box

Example 8.3. Let $\alpha \in [0, +\infty)$, let C be a nonempty closed convex subset of H, let $B: H \to H$ be α -cocoercive, suppose that the set Z of solutions to the variational inequality

find
$$
x \in C
$$
 such that $(\forall y \in C) \langle x - y | Bx \rangle \le 0$ (8.20)

is not empty, and let Z^* be the set of solutions to the dual problem

find
$$
x^* \in \mathcal{H}
$$
 such that $0 \in -\partial \sigma_C(-x^*) + B^{-1}x^*$. (8.21)

Let $x_0 \in \mathcal{H}$, let $\varepsilon \in [0, \alpha/(\alpha+1)]$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (2-\varepsilon)\alpha]$, and suppose that $(\mu_n)_{n \in \mathbb{N}}$ satisfies [\(8.2\)](#page-78-0). Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nb_n^* = \gamma_n B x_n \\
w_n = \text{proj}_C (x_n - b_n^*) \\
x_{n+1} = x_n + \mu_n (w_n - x_n).\n\end{cases}
$$
\n(8.22)

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z and $(Bx_n)_{n \in \mathbb{N}}$ converges strongly to the unique point in Z^* .

Proof. Use Example [2.36](#page-20-1) and [\(2.2\)](#page-5-0), and set $f = \iota_C$ in Example [8.2.](#page-80-0) \Box

The following example focuses on the minimization in the setting of Problem [3.5](#page-24-5)[\(ii\)](#page-24-6). This framework has found a multitude of applications, especially in the areas of signal processing and machine learning [\(Argyriou](#page-127-2) *et al.* [2012,](#page-127-2) [Beck and](#page-128-0) [Teboulle](#page-128-0) [2010,](#page-128-0) [Chan, Setzer and Steidl](#page-131-1) [2008,](#page-131-1) [Combettes and Wajs](#page-133-2) [2005,](#page-133-2) [Combettes](#page-133-3) *[et al.](#page-133-3)* [2018,](#page-133-3) [Dexter, Tran and Webster](#page-134-1) [2022,](#page-134-1) [Jenatton](#page-137-0) *et al.* [2011,](#page-137-0) [Vaiter](#page-143-1) *et al.* [2018\)](#page-143-1).

Example 8.4. Let $\beta \in [0, +\infty)$, let $f \in \Gamma_0(\mathcal{H})$ and let $g : \mathcal{H} \to \mathbb{R}$ be convex and differentiable. Suppose that ∇g is β -Lipschitzian and that the set Z of solutions to the problem

$$
\underset{x \in \mathcal{H}}{\text{minimize}} \quad f(x) + g(x) \tag{8.23}
$$

is not empty, and let Z^* be the set of solutions to the dual problem

$$
\underset{x^* \in \mathcal{H}}{\text{minimize}} \quad f^*(-x^*) + g^*(x^*). \tag{8.24}
$$

Let $x_0 \in \mathcal{H}$, let $\varepsilon \in [0, 1/(\beta + 1)]$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (2 - \varepsilon)/\beta]$, and suppose that

$$
(\forall n \in \mathbb{N}) \quad \varepsilon \le \mu_n \le (1 - \varepsilon) \frac{4 - \beta \gamma_n}{2}.
$$
\n
$$
(8.25)
$$

Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nb_n^* = \gamma_n \nabla g(x_n) \\
w_n = \text{prox}_{\gamma_n f}(x_n - b_n^*) \\
x_{n+1} = x_n + \mu_n (w_n - x_n).\n\end{cases}
$$
\n(8.26)

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z and $(\nabla g(x_n))_{n \in \mathbb{N}}$ converges strongly to the unique point in Z^* .

Proof. The claim is established by applying Theorem [8.1\(](#page-78-6)[i\)](#page-78-2) with $A = \partial f$ (see Example [2.12\)](#page-13-0) and $B = \nabla g$ (see Lemma [2.2\)](#page-9-0). \Box

Remark 8.5. In some applications, it may be of interest to quantify the asymptotic behaviour of the function values $(f(x_n)+g(x_n))_{n\in\mathbb{N}}$ produced by [\(8.26\)](#page-81-0). This topic has been the focus of a lot of interest since the publication of the influential papers by [Beck and Teboulle](#page-128-1) [\(2009](#page-128-1)*b*,*[a](#page-128-2)*) and [Chambolle and Dossal](#page-131-2) [\(2015\)](#page-131-2); see [Garrigos,](#page-135-1) [Rosasco and Villa](#page-135-1) [\(2023\)](#page-135-1) and its bibliography for recent results on the unrelaxed implementation of [\(8.26\)](#page-81-0) with constant proximal parameters.

The following example, taken from [Combettes and Wajs](#page-133-2) [\(2005\)](#page-133-2), models linear inverse problems in which the prior knowledge is modelled by penalizing the coefficients of the decomposition of the ideal solution in an orthonormal basis; see [Combettes, Salzo and Villa](#page-133-3) [\(2018\)](#page-133-3), [Daubechies, Defrise and De Mol](#page-134-2) [\(2004\)](#page-134-2) and [Figueiredo and Nowak](#page-135-2) [\(2003\)](#page-135-2) for special cases.

<https://doi.org/10.1017/S0962492923000065>Published online by Cambridge University Press

Example 8.6. Suppose that H is separable, let $(e_k)_{k \in \mathbb{K}}$ be an orthonormal basis of H, let $y \in \mathcal{G}$, suppose that $0 \neq L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$, and let $(\phi_k)_{k \in \mathbb{K}}$ be functions in $\Gamma_0(\mathbb{R})$ such that $(\forall k \in \mathbb{K}) \phi_k \geq 0 = \phi_k(0)$. Suppose that the set Z of solutions to the problem

$$
\underset{x \in \mathcal{H}}{\text{minimize}} \quad \sum_{k \in \mathbb{K}} \phi_k(\langle x \mid e_k \rangle) + \frac{1}{2} \|Lx - y\|^2 \tag{8.27}
$$

is not empty. Let $x_0 \in \mathcal{H}$, let $\varepsilon \in [0, 1/(||L||^2 + 1)[$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (2-\varepsilon)/||L||^2]$, and suppose that

$$
(\forall n \in \mathbb{N}) \quad \varepsilon \le \mu_n \le (1 - \varepsilon) \frac{4 - ||L||^2 \gamma_n}{2}.
$$
\n
$$
(8.28)
$$

Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nb_n^* = \gamma_n L^* (Lx_n - y) \\
w_n = \sum_{k \in \mathbb{K}} (\text{prox}_{\gamma_n \phi_k} \langle x_n - b_n^* | e_k \rangle) e_k \\
x_{n+1} = x_n + \mu_n (w_n - x_n).\n\end{cases}
$$
\n(8.29)

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z.

Proof. Set $f: x \mapsto \sum_{k \in \mathbb{K}} \phi_k(\langle x | e_k \rangle)$ and $g: x \mapsto ||Lx - y||^2/2$. Then, as shown in [Combettes and Wajs](#page-133-2) [\(2005,](#page-133-2) Example 2.19), $f \in \Gamma_0(\mathcal{H})$ and $prox_{\gamma f}: x \mapsto$ $\sum_{k\in\mathbb{K}}$ (prox $\gamma_n\phi_k$ $\langle x \mid e_k \rangle$) e_k . On the other hand, g is convex and differentiable and $\nabla g: x \mapsto L^*(Lx - y)$ is $||L||^2$ -Lipschitzian. Altogether, the conclusion follows from Example [8.4.](#page-81-1) \Box

Next, we specialize Example [8.4](#page-81-1) to the gradient-projection method, which minimizes a smooth function over a convex set (see Example [3.6\)](#page-24-7) and goes back to [Goldstein](#page-136-0) [\(1964\)](#page-136-0) and [Levitin and Polyak](#page-138-0) [\(1966\)](#page-138-0).

Example 8.7. Let $\beta \in [0, +\infty)$, let C be a nonempty closed convex subset of H, and let $g: \mathcal{H} \to \mathbb{R}$ be convex and differentiable. Suppose that ∇g is β -Lipschitzian and that the set Z of solutions to the problem

$$
\underset{x \in C}{\text{minimize}} g(x) \tag{8.30}
$$

is not empty, and let Z^* be the set of solutions to the dual problem

$$
\underset{x^* \in \mathcal{H}}{\text{minimize}} \ \sigma(-x^*) + g^*(x^*). \tag{8.31}
$$

Let $x_0 \in \mathcal{H}$, let $\varepsilon \in [0, 1/(\beta + 1)]$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (2 - \varepsilon)/\beta]$, and suppose that $(\mu_n)_{n \in \mathbb{N}}$ satisfies [\(8.25\)](#page-81-2). Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nb_n^* = \gamma_n \nabla g(x_n) \\
w_n = \text{proj}_C(x_n - b_n^*) \\
x_{n+1} = x_n + \mu_n (w_n - x_n).\n\end{cases}
$$
\n(8.32)

Then $(x_n)_{n\in\mathbb{N}}$ converges weakly to a point in Z and $(\nabla g(x_n))_{n\in\mathbb{N}}$ converges strongly to the unique point in Z^* .

Proof. Set $f = \iota_C$ in Example [8.4.](#page-81-1) Alternatively, set $B = \nabla g$ in Example [8.3.](#page-80-1) \Box

Remark 8.8. [Attouch, Peypouquet and Redont](#page-127-3) [\(2018\)](#page-127-3) studied the backward– forward iterations

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\np_n = J_{\gamma A} x_n \\
q_n = p_n - \gamma B p_n \\
x_{n+1} = x_n + \mu_n (q_n - x_n),\n\end{cases}
$$
\n(8.33)

Ī and showed them to be related to the forward–backward iterations applied to Yosida envelopes of B and A .

8.3. Haugazeau-like algorithm

As seen in [Combettes and Wajs](#page-133-2) [\(2005,](#page-133-2) Remark 5.12), the strong convergence of $(x_n)_{n \in \mathbb{N}}$ in Theorem [8.1](#page-78-6)[\(i\)](#page-83-0) may fail. Item (i) below on the strong convergence of a best approximation forward–backward algorithm extends Theorem 5.6(i) and Remark 5.5 of [Combettes and Hirstoaga](#page-132-1) [\(2005\)](#page-132-1), where $(\forall n \in \mathbb{N}) \gamma_n = \gamma \in (0, 2\alpha)$ and $\mu_n \leq 1$.

Theorem 8.9. Let $\alpha \in]0, +\infty[$, let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, and let $B: \mathcal{H} \to \mathcal{H}$ be α -cocoercive. Let $\varepsilon \in [0, \min\{1/2, 2\alpha\}]$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, 2\alpha]$, and let

$$
(\forall n \in \mathbb{N}) \quad \varepsilon \le \mu_n \le \frac{4\alpha - \gamma_n}{4\alpha}.\tag{8.34}
$$

Suppose that the set Z of solutions to the problem

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + Bx$ (8.35)

is not empty and let Z^* be the set of solutions to the dual

find
$$
x^* \in \mathcal{H}
$$
 such that $0 \in -A^{-1}(-x^*) + B^{-1}x^*$. (8.36)

Let $x_0 \in \mathcal{H}$ and iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nb_n^* = \gamma_n B x_n \\
w_n = J_{\gamma_n} A(x_n - b_n^*) \\
x_{n+1} = Q(x_0, x_n, x_n + \mu_n (w_n - x_n)),\n\end{cases}
$$
\n(8.37)

J where Q is defined in Lemma [4.6.](#page-33-0) Then the following hold:

- (i) $(x_n)_{n \in \mathbb{N}}$ converges strongly to proj_Z x_0 .
- (ii) Z^* contains a single point \overline{x}^* and $(Bx_n)_{n \in \mathbb{N}}$ converges strongly to \overline{x}^* .

Proof. We apply Theorem [4.14](#page-41-0) in the setting of [\(8.6\)](#page-78-7), using the same variables as in [\(8.8\)](#page-79-0) and $(\lambda_n)_{n \in \mathbb{N}}$ defined as in [\(8.9\)](#page-79-4). Then [\(8.11\)](#page-79-5) holds and

$$
(\forall n \in \mathbb{N}) \quad \varepsilon \le \frac{4\alpha\varepsilon}{4\alpha - \varepsilon} \le \lambda_n \le 1. \tag{8.38}
$$

Therefore the sequence $(x_n)_{n\in\mathbb{N}}$ produced by [\(8.37\)](#page-83-1) coincides with that of [\(4.44\)](#page-41-1). Hence, by Theorem [4.14](#page-41-0)[\(i\)](#page-41-2),

$$
w_n - x_n \to 0. \tag{8.39}
$$

[\(i\)](#page-83-0) This follows from Theorem [4.14](#page-41-0)[\(ii\)](#page-41-3) since, as in the proof of Theorem [8.1\(](#page-78-6)[i\)](#page-78-2), its conditions [\(iib\)](#page-41-4) and [\(iid\)](#page-41-5) are fulfilled.

[\(ii\)](#page-83-2) Since *B* is continuous, [\(i\)](#page-83-0) and Theorem [8.1\(](#page-78-6)[ii\)](#page-78-3) imply that $Bx_n \to B(\text{proj}_Z x_0) \in$ Z^* , where Z^* is a singleton. \Box

8.4. Special cases and variants

8.4.1. Projected Landweber method

In inverse problems, constrained least-squares estimation has a long history [\(Ben](#page-128-3)[ning and Burger](#page-128-3) [2018,](#page-128-3) [Bertero](#page-128-4) *et al.* [1997,](#page-128-4) [Eicke](#page-135-3) [1992,](#page-135-3) [Neubauer](#page-140-0) [1988,](#page-140-0) [Phillips](#page-140-1) [1962\)](#page-140-1). We address the numerical solution of this problem from the viewpoint of the forward–backward algorithm to obtain a relaxed version of the projected Landweber method with iteration-dependent parameters.

Proposition 8.10. Let G be a real Hilbert space, suppose that $0 \neq L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$, let $y \in \mathcal{G}$, and let C be a closed convex subset of H such that the set Z of solutions to the problem

minimize
$$
\frac{1}{2} ||Lx - y||^2
$$
 (8.40)

is not empty. Let $x_0 \in \mathcal{H}$, let $\varepsilon \in]0, 1/(\Vert L \Vert^2 + 1)[$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (2 - \varepsilon) / ||L||^2]$, and suppose that $(\mu_n)_{n \in \mathbb{N}}$ satisfies [\(8.28\)](#page-82-1). Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nb_n^* = \gamma_n L^* (Lx_n - y) \\
w_n = \text{proj}_C (x_n - b_n^*) \\
x_{n+1} = x_n + \mu_n (w_n - x_n).\n\end{cases}
$$
\n(8.41)

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z.

Proof. Apply Example [8.7](#page-82-0) with $g: x \mapsto ||Lx - y||^2/2$. \Box

Proposition [8.10](#page-84-0) was established in [Eicke](#page-135-3) [\(1992,](#page-135-3) Section 3.1) with ($\forall n \in \mathbb{N}$) $\lambda_n =$ 1 and $\gamma_n = \gamma \in]0, 2/||L||^2$. There, it was also conjectured that the convergence was strong, which was disproved in [Combettes and Wajs](#page-133-2) [\(2005,](#page-133-2) Remark 5.12). This motivates the following result.

Proposition 8.11. Let G be a real Hilbert space, suppose that $0 \neq L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$, let $y \in \mathcal{G}$, let C be a closed convex subset of H, and suppose that the set Z of solutions to [\(8.40\)](#page-84-1) is not empty. Let $x_0 \in \mathcal{H}$, let $\varepsilon \in]0, \min\{1/2, 2/\|L\|^2\}$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, 2/\Vert L \Vert^2]$, and suppose that $(\forall n \in \mathbb{N}) \varepsilon \le \mu_n \le 1 - \|L\|^2 \gamma_n/4$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nb_n^* = \gamma_n L^* (Lx_n - y) \\
w_n = \text{proj}_C (x_n - b_n^*) \\
x_{n+1} = \mathsf{Q}(x_0, x_n, x_n + \mu_n (w_n - x_n)),\n\end{cases}
$$
\n(8.42)

where Q is defined in Lemma [4.6\(](#page-33-0)[ii\)](#page-33-1). Then $(x_n)_{n \in \mathbb{N}}$ converges strongly to proj_Z x_0 .

Proof. Follow the pattern of the proof of Proposition [8.10](#page-84-0) and use Example [2.36](#page-20-1) to apply Theorem [8.9\(](#page-83-3)[i\)](#page-83-0) with $A = N_C$ and $B: x \mapsto L^*(Lx - y)$. \Box

Here is an application of Proposition [8.10](#page-84-0) to the problem of finding the best approximation to a point from a linearly transformed convex set.

Example 8.12. Consider the setting of Proposition [8.10](#page-84-0) with the assumption that $L(C)$ is closed, which guarantees that [\(8.40\)](#page-84-1) admits solutions. Then $x_n \to x$, where x solves [\(8.40\)](#page-84-1). Furthermore, if we set $p = Lx$, then $p = \text{proj}_{L(C)} y$. Hence, upon rewriting [\(8.41\)](#page-84-2) as

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nq_n = Lx_n \\
b_n^* = \gamma_n L^*(q_n - y) \\
w_n = \text{proj}_C(x_n - b_n^*) \\
x_{n+1} = x_n + \mu_n (w_n - x_n),\n\end{cases}
$$
\n(8.43)

and invoking the weak continuity of L, we conclude that $q_n \to \text{proj}_{L(C)} y$.

Example 8.13. Let G be a real Hilbert space, and suppose that $0 \neq L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$ and that ran *L* is closed. Additionally, let $x_0 \in \mathcal{H}$, let $\varepsilon \in]0, 1/(||L||^2 + 1)[$, and let $(\nu_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (2 - \varepsilon)/||L||^2]$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nq_n = Lx_n \\
x_{n+1} = x_n - v_n L^* q_n,\n\end{cases}
$$
\n(8.44)

 \Box

and let q be the minimal-norm element of ran L. Then $q_n \rightarrow q$.

Proof. Apply Example [8.12](#page-85-0) with $C = H$ and $y = 0$.

The next example is about a composite best approximation problem.

Example 8.14. Let G be a real Hilbert space, let $y \in G$, and let $0 \lt p \in \mathbb{N}$. For every $k \in \{1, \ldots, p\}$, let \mathcal{H}_k be a real Hilbert space, let C_k be a nonempty closed convex subset of \mathcal{H}_k , let $0 \neq L_k \in \mathcal{B}(\mathcal{H}_k, \mathcal{G})$, and let $x_{k,0} \in \mathcal{H}_k$. Suppose that $\sum_{k=1}^{p} L_k(C_k)$ is closed and set $\beta = \sum_{k=1}^{p} ||L_k||^2$. Furthermore, let

 $\varepsilon \in [0, 1/(\beta + 1)]$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (2 - \varepsilon)/\beta]$, and suppose that $(\mu_n)_{n \in \mathbb{N}}$ satisfies [\(8.25\)](#page-81-2). Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nq_n = \sum_{k=1}^p L_k x_{k,n} \\
\text{for } k = 1, ..., p \\
b_{k,n}^* = \gamma_n L_k^* (q_n - y) \\
w_{k,n} = \text{proj}_{C_k} (x_{k,n} - b_{k,n}^*) \\
x_{k,n+1} = x_{k,n} + \mu_n (w_{k,n} - x_{k,n}).\n\end{cases}
$$
\n(8.45)

Then $q_n \to \text{proj}_{\sum_{k=1}^p L_k(C_k)} y$.

Proof. Set $\mathcal{H} = \mathcal{H}_1 \oplus \cdots \oplus \mathcal{H}_p$, $\mathcal{C} = C_1 \times \cdots \times C_p$ and

$$
L: \mathcal{H} \to \mathcal{G}: (x_k)_{1 \le k \le p} \mapsto \sum_{k=1}^p L_k x_k. \tag{8.46}
$$

Then $\text{proj}_{\mathbf{C}} : (x_k)_{1 \leq k \leq p} \mapsto (\text{proj}_{\mathbf{C}_k} x_k)_{1 \leq k \leq p}$ (see Examples [2.36](#page-20-1) and [2.37\)](#page-20-2), $||L||^2 =$ β and $L^* \colon \mathcal{G} \to \mathcal{H} \colon y^* \mapsto (L_1^*$ ${}_{1}^{*}y^{*}, \ldots, L_{p}^{*}y^{*}$). Altogether, the result is an applica-tion of Example [8.12](#page-85-0) to C and \overline{L} in $\overline{\mathcal{H}}$. \Box

As an application of Example [8.14,](#page-85-1) we address the problem of computing the best approximation from the Minkowski sum of closed convex sets; see [Bauschke,](#page-128-5) [Bùi and Wang](#page-128-5) [\(2019\)](#page-128-5), [Eaves](#page-134-3) [\(1984\)](#page-134-3), [Martínez-Legaz and Seeger](#page-139-2) [\(1994\)](#page-139-2), [Qin and](#page-141-0) [An](#page-141-0) [\(2019\)](#page-141-0), [Seeger](#page-142-1) [\(1998\)](#page-142-1), [Wang, Zhang and Zhang](#page-144-0) [\(2020\)](#page-144-0) and [Won, Xu and Lange](#page-144-1) [\(2019\)](#page-144-1) for instances of decompositions with respect to such sums.

Example 8.15. Let $z \in \mathcal{H}$ and $0 < p \in \mathbb{N}$. For every $k \in \{1, ..., p\}$, let C_k be a nonempty closed convex subset of H and let $x_{k,0} \in \mathcal{H}$. Suppose that $\sum_{k=1}^{p} C_k$ is closed, let $\varepsilon \in [0, 1/(p+1)]$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (2-\varepsilon)/p]$, and suppose that $(\forall n \in \mathbb{N}) \varepsilon \leq \mu_n \leq (1 - \varepsilon)(2 - p\gamma_n/2)$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nq_n = \sum_{k=1}^p x_{k,n} \\
b_n^* = \gamma_n (q_n - z) \\
\text{for } k = 1, ..., p \\
\begin{bmatrix}\nw_{k,n} = \text{proj}_{C_k} (x_{k,n} - b_n^*) \\
x_{k,n+1} = x_{k,n} + \mu_n (w_{k,n} - x_{k,n}).\n\end{bmatrix}\n\end{cases}
$$
\n(8.47)

Then $q_n \to \text{proj}_{\sum_{k=1}^p C_k}$ z.

Proof. Apply Example [8.14](#page-85-1) with $G = H$, $y = z$ and $(\forall k \in \{1, ..., p\})$ $H_k = H$ and $L_k = Id$.

8.4.2. Partial Yosida approximation to inconsistent common zero problems

We extend a framework proposed in Combettes (2004, Section 6.3), where no linear transformations were present. We start with the following composite common zero problem; see [Byrne, Censor, Gibali and Reich](#page-131-3) [\(2012\)](#page-131-3) for a special case.

Problem 8.16. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone and let $0 < p \in \mathbb{N}$. For every $k \in \{1, ..., p\}$, let \mathcal{G}_k be a real Hilbert space, let $B_k: \mathcal{G}_k \to 2^{\mathcal{G}_k}$ be maximally monotone, and suppose that $0 \neq L_k \in \mathcal{B}(\mathcal{H}, \mathcal{G}_k)$. The objective is to

find
$$
x \in \text{zer } A
$$
 such that $(\forall k \in \{1, ..., p\})$ $L_k x \in \text{zer } B_k$. (8.48)

Example 8.17. Suppose that, in Problem [8.16,](#page-86-0) $A = N_C$, where C is a nonempty closed convex subset of H, and, for every $k \in \{1, ..., p\}$, $B_k = N_{D_k}$, where D_k is a nonempty closed convex subset of \mathcal{G}_k . Then [\(8.48\)](#page-87-0) is the *split feasibility problem* [\(Reich, Truong and Mai](#page-141-1) [2020\)](#page-141-1)

find
$$
x \in C
$$
 such that $(\forall k \in \{1, ..., p\}) L_k x \in D_k$. (8.49)

Example 8.18. Suppose that, in Problem [8.16,](#page-86-0) $A = \partial f$, where $f \in \Gamma_0(\mathcal{H})$, and, for every $k \in \{1, ..., p\}$, $\mathcal{G}_k = \mathcal{H}$, $L_k = \text{Id}$ and $B_k = \partial f_k$, where $f_k \in \Gamma_0(\mathcal{H})$. Then [\(8.48\)](#page-87-0) becomes

find
$$
x \in (\text{Argmin } f) \cap \bigcap_{k=1}^{p} \text{Argmin } f_k.
$$
 (8.50)

Example 8.19. Suppose that, in Problem [8.16,](#page-86-0) $A = N_C$, where C is a nonempty closed convex subset of H, and, for every $k \in \{1, \ldots, p\}$, $B_k = (\text{Id} - F_k + r_k)^{-1} - \text{Id}$, where $F_k: \mathcal{G}_k \to \mathcal{G}_k$ is firmly nonexpansive and $r_k \in \mathcal{G}_k$. Then [\(8.48\)](#page-87-0) becomes

find
$$
x \in C
$$
 such that $(\forall k \in \{1, ..., p\}) F_k(L_k x) = r_k.$ (8.51)

Note that the operators $(\text{Id} - F_k + r_k)_{1 \leq k \leq p}$ are firmly nonexpansive as well, which makes the operators $(B_k)_{1 \leq k \leq p}$ maximally monotone by Lemma [2.34](#page-20-3)[\(iii\)](#page-20-4). This formulation was investigated in [Combettes and Woodstock](#page-133-4) [\(2022\)](#page-133-4) in the context of recovering a signal in C from p nonlinear observations modelled as outputs of Wiener systems (see also Example [5.12\)](#page-48-0).

Our focus here is on situations in which [\(8.48\)](#page-87-0) is not guaranteed to have solutions; see [Censor and Zaknoon](#page-131-4) [\(2018\)](#page-131-4), [Combettes and Bondon](#page-132-3) [\(1999\)](#page-132-3), [Combettes and](#page-132-4) [Glaudin](#page-132-4) [\(2019\)](#page-132-4) and [Goldburg and Marks II](#page-136-1) [\(1985\)](#page-136-1) for concrete illustrations. In such environments, it is natural to approximate it by a more general problem, which exhibits better regularity properties and admits solutions. We propose the following relaxation of Problem [8.16,](#page-86-0) in which dom A serves as a hard constraint.

Problem 8.20. Consider the setting of Problem [8.16](#page-86-0) and let $(\rho_k)_{1 \leq k \leq p}$ and $(\omega_k)_{1 \leq k \leq p}$ be in]0, + ∞ [. The objective is to solve the *partial Yosida approximation*

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + \sum_{k=1}^{p} \omega_k L_k^*({}^{\rho_k}B_k(L_k x))$ (8.52)

to Problem [8.16.](#page-86-0)

The fact that Problem [8.20](#page-87-1) is an appropriate relaxation of Problem [8.16](#page-86-0) is supported by the following argument.

Proposition 8.21. Suppose that the set of solutions to Problem [8.16](#page-86-0) is not empty. Then it coincides with the set of solutions to Problem [8.20.](#page-87-1)

Proof. Let \bar{x} be a solution to Problem [8.16.](#page-86-0) Then [\(2.22\)](#page-7-1) yields

$$
0 = -\sum_{k=1}^{p} \omega_k L_k^* \left(\ell^{\rho_k} B_k(L_k \overline{x})\right) \in A\overline{x},\tag{8.53}
$$

which shows that \bar{x} solves Problem [8.20.](#page-87-1) Now let x be a solution to Problem 8.20. Then

$$
-\sum_{k=1}^{p} \omega_k L_k^*({}^{\rho_k} B_k(L_k x)) \in Ax.
$$
 (8.54)

It follows from (8.53) , (8.54) , the monotonicity of A and the cocoercivity of the operators $({}^{\rho_k}B_k)_{1\leq k\leq p}$ (see Example [2.7\)](#page-12-0) that

$$
0 \ge \left\langle x - \overline{x} \right| \sum_{k=1}^{p} \omega_k L_k^* (P^k B_k(L_k x)) - \sum_{k=1}^{p} \omega_k L_k^* (P^k B_k(L_k \overline{x})) \right\rangle
$$

\n
$$
= \sum_{k=1}^{p} \omega_k \left\langle L_k x - L_k \overline{x} \right| P^k B_k(L_k x) - P^k B_k(L_k \overline{x}) \right\rangle
$$

\n
$$
\ge \sum_{k=1}^{p} \omega_k \rho_k ||^{p_k} B_k(L_k x) - P^k B_k(L_k \overline{x})||^2
$$

\n
$$
= \sum_{k=1}^{p} \omega_k \rho_k ||^{p_k} B_k(L_k x) ||^2.
$$
 (8.55)

Hence, we deduce from [\(2.22\)](#page-7-1) that $(\forall k \in \{1, ..., p\})$ $L_k x \in \text{zer}^{\rho_k} B_k = \text{zer} B_k$. In view of (8.54) , we conclude that x solves Problem [8.16.](#page-86-0) \Box

Remark 8.22. It should be emphasized that Problem [8.20](#page-87-1) is a relaxation of Problem [8.16,](#page-86-0) and not of the inclusion

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + \sum_{k=1}^{p} \omega_k L_k^*(B_k(L_k x))$. (8.56)

In particular, $zer(A + ^{\rho}B) \neq zer(A + B)$ when $zer(A + B) \neq \emptyset$. However, the problem of finding a zero of $A + P B$ can be regarded as a regularization of that of finding a zero of $A + B$ in the sense that solutions to the former approaches a particular solution of the latter as $\rho \rightarrow 0$ [\(Mahey and Pham](#page-138-3) [1993,](#page-138-3) [Mercier](#page-139-1) [1980,](#page-139-1) [Moudafi](#page-139-3) [2000\)](#page-139-3).

Example 8.23. Consider the setting of Example [8.17](#page-87-2) and let $(\forall k \in \{1, ..., p\})$ $\rho_k = 1$. Then [\(8.52\)](#page-87-3) relaxes the possibly inconsistent problem [\(8.49\)](#page-87-4) to the problem

$$
\underset{x \in C}{\text{minimize}} \quad \sum_{k=1}^{p} \omega_k d_{D_k}^2(L_k x). \tag{8.57}
$$

- (i) Assume that, for every $k \in \{1, ..., p\}$, $\mathcal{G}_k = \mathcal{H}$ and $L_k = \text{Id}$. Then [\(8.57\)](#page-89-0) is the relaxed formulation of [Combettes and Bondon](#page-132-3) [\(1999\)](#page-132-3).
- (ii) Assume that $\mathcal{H} = \mathbb{R}^N$, $C = \mathbb{R}^N$, and, for every $k \in \{1, ..., p\}$, $\mathcal{G}_k = \mathbb{R}$, $L_k: x \mapsto u_k^{\top}x$ with $u_k \in \mathbb{R}^N$, and $D_k = \{\eta_k\}$ with $\eta_k \in \mathbb{R}$. Let $U \in \mathbb{R}^{p \times N}$ be the matrix with rows u_1^{\dagger} $\overline{u}_1^{\top}, \ldots, u_p^{\top}$ and set $y = (\eta_k)_{1 \leq k \leq p}$. Then [\(8.49\)](#page-87-4) amounts to solving the linear system $Ux = y$ and [\(8.57\)](#page-89-0) to minimizing $x \mapsto ||Ux - y||^2$. This least-squares relaxation was proposed by [Legendre](#page-138-4) [\(1805\)](#page-138-4) and rediscovered by [Gauss](#page-135-4) [\(1809\)](#page-135-4).

Example 8.24. Consider the setting of Example [8.18](#page-87-5) and recall that $(\forall k \in \mathbb{R})$ $\{(1,\ldots,p\})^{\rho_k}(\partial f_k) = \{\nabla(\rho_k f_k)\}\)$ [\(Bauschke and Combettes](#page-127-1) [2017,](#page-127-1) Example 23.3). Thus, [\(8.52\)](#page-87-3) relaxes the possibly inconsistent problem [\(8.50\)](#page-87-6) to the problem

$$
\underset{x \in \mathcal{H}}{\text{minimize}} \quad f(x) + \sum_{k=1}^{p} \omega_k \binom{\rho_k}{f_k(x)}.
$$
\n(8.58)

This formulation arises in particular in federated learning [\(Pathak and Wainwright](#page-140-2) [2020\)](#page-140-2).

Example 8.25. Consider the setting of Example [8.19](#page-87-7) and let ($\forall k \in \{1, \ldots, p\}$) $\rho_k = 1$. Then it follows from Example [2.14](#page-13-1) and [\(2.21\)](#page-7-2) that [\(8.52\)](#page-87-3) relaxes the possibly inconsistent problem [\(8.51\)](#page-87-8) to the variational inequality problem (see Problem [3.3\)](#page-24-4)

find
$$
x \in C
$$
 such that $(\forall y \in C)$ $\sum_{k=1}^{p} \omega_k \langle L_k(y - x) | F_k(L_k x) - r_k \rangle \ge 0$, (8.59)

which is precisely the relaxation of [\(8.51\)](#page-87-8) studied in [Combettes and Woodstock](#page-133-4) [\(2022\)](#page-133-4).

Let us now solve Problem [8.20](#page-87-1) with the forward–backward algorithm.

Proposition 8.26. Consider the setting of Problem [8.20,](#page-87-1) suppose that its set Z of solutions is not empty, and set

$$
\alpha = \frac{1}{\sum_{k=1}^{P} \frac{\omega_k ||L_k||^2}{\rho_k}}.
$$
\n(8.60)

Let $x_0 \in \mathcal{H}$, let $\varepsilon \in [0, \alpha/(\alpha+1)]$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (2-\varepsilon)\alpha]$, and

suppose that $(\mu_n)_{n \in \mathbb{N}}$ satisfies [\(8.2\)](#page-78-0). Iterate

for
$$
n = 0, 1, ...
$$

\nfor $k = 1, ..., p$
\n
$$
\begin{cases}\ny_{k,n} = L_k x_n \\
p_{k,n} = \rho_k^{-1} (y_{k,n} - J_{\rho_k} B_k y_{k,n})\n\end{cases}
$$
\n
$$
b_n^* = \gamma_n \sum_{\substack{k=1 \ k \neq 1}}^n \omega_k L_k^* p_{k,n}
$$
\n
$$
w_n = J_{\gamma_n} A(x_n - b_n^*)
$$
\n
$$
x_{n+1} = x_n + \mu_n (w_n - x_n).
$$
\n(8.61)

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z.

Proof. Define

$$
B = \sum_{k=1}^{p} \omega_k L_k^* \circ (^{\rho_k} B_k) \circ L_k. \tag{8.62}
$$

Then it follows from [Bauschke and Combettes](#page-127-1) [\(2017,](#page-127-1) Proposition 4.12) and Ex-ample [2.7](#page-12-0) that B is α -cocoercive. Since [\(8.61\)](#page-90-0) is a specialization of [\(8.5\)](#page-78-1), Theorem [8.1](#page-78-6)[\(i\)](#page-78-2) furnishes the desired conclusion. \Box

8.4.3. Backward–backward splitting

We focus on the following special case of Problem [8.20.](#page-87-1)

Problem 8.27. Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, and let $\rho \in [0, +\infty)$. The objective is to

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + \rho Bx$. (8.63)

Proposition 8.28. Consider the setting of Problem [8.27](#page-90-1) under the assumption that $Z = \text{zer}(A + \rho B) \neq \emptyset$. Let $x_0 \in \mathcal{H}$, let $\varepsilon \in [0, \rho/(\rho+1)]$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (2 - \varepsilon)\rho]$, and suppose that $(\mu_n)_{n \in \mathbb{N}}$ satisfies [\(8.2\)](#page-78-0) with $\alpha = \rho$. **Iterate**

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n p_n = \rho^{-1}(x_n - J_{\rho B} x_n) \\
 w_n = J_{\gamma_n A}(x_n - \gamma_n p_n) \\
 x_{n+1} = x_n + \mu_n (w_n - x_n).\n\end{cases}
$$
\n(8.64)

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z.

Proof. Apply Proposition [8.26](#page-89-1) with $p = 1$, $\mathcal{G}_1 = \mathcal{H}$, $L_1 = \text{Id}$, $B_1 = B$, $\omega_1 = 1$ and \Box $\rho_1 = \rho$.

Example 8.29. In particular, if we execute [\(8.64\)](#page-90-2) with, for every $n \in \mathbb{N}$, $\gamma_n = \rho$ and $\mu_n = 1$, then

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = J_{\rho A}(J_{\rho B} x_n). \tag{8.65}
$$

This recursion is known as the *backward–backward algorithm*, as it alternates two backward Euler steps. As derived above, it is a special case of [\(8.61\)](#page-90-0) and therefore of the forward–backward algorithm [\(8.5\)](#page-78-1). Its asymptotic behaviour has been studied by [Bauschke](#page-128-6) *et al.* [\(2005\)](#page-128-6) and [Mercier](#page-139-1) [\(1980\)](#page-139-1); see also [Lions](#page-138-5) [\(1978\)](#page-138-5) and [Passty](#page-140-3) [\(1979\)](#page-140-3) for ergodic convergence.

Example 8.30. Let f and g be functions in $\Gamma_0(\mathcal{H})$. In Problem [8.27,](#page-90-1) suppose that $A = \partial f$ and $B = \partial g$. Then, as in Example [8.24,](#page-89-2) [\(8.65\)](#page-90-3) becomes

$$
\underset{x \in \mathcal{H}}{\text{minimize}} \quad f(x) + \,^{\rho} g(x) \tag{8.66}
$$

and [\(8.65\)](#page-90-3) reduces to the *alternating proximal point algorithm*

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = \text{prox}_{\rho f}(\text{prox}_{\rho g} x_n). \tag{8.67}
$$

This method was first investigated in [Acker and Prestel](#page-126-0) [\(1980\)](#page-126-0), with further developments in [Bauschke](#page-128-6) *et al.* [\(2005\)](#page-128-6).

Example 8.31. Let C and D be nonempty closed convex subsets of H . In Ex-ample [8.30,](#page-91-0) suppose that $f = \iota_C$ and $g = \iota_D$. Then [\(8.67\)](#page-91-1) is the problem of finding a point in C at minimal distance from D and [\(8.67\)](#page-91-1) yields the *alternating projection method*

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = \text{proj}_C(\text{proj}_D x_n), \tag{8.68}
$$

which was first investigated in[Cheney and Goldstein](#page-132-5) [\(1959](#page-132-5)*b*). Its weak convergence was established in [Gubin](#page-136-2) *et al.* [\(1967,](#page-136-2) Theorem 2)

Example 8.32. Let $f \in \Gamma_0(\mathcal{H}), h \in \Gamma_0(\mathcal{H}), z \in \mathcal{H}$ and $\rho \in [0, +\infty[$. The problem is to

minimize
$$
f(x) + h(w) + \frac{1}{2\rho} ||x + w - z||^2
$$
. (8.69)

Following [Combettes and Wajs](#page-133-2) [\(2005,](#page-133-2) Section 4.4), set $g: y \mapsto h(z - y)$. Then, with the change of variable $y = z - w$, the objective of [\(8.69\)](#page-91-2) is to

minimize
$$
f(x) + g(y) + \frac{1}{2\rho} ||x - y||^2
$$
, (8.70)

which is precisely [\(8.66\)](#page-91-3) in terms of the variable x. Now let $x_0 \in \mathcal{H}$, let $\varepsilon \in \mathcal{H}$ $[0, \rho/(\rho+1)]$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (2-\varepsilon)\rho]$, and let $(\mu_n)_{n \in \mathbb{N}}$ be a sequence in [ε , 1]. Applying algorithm [\(8.64\)](#page-90-2) to $A = \partial f$ and $B = \partial g$, and noting that $J_{\rho B} = \text{prox}_{\rho g}$: $x \mapsto z - \text{prox}_{\rho h}(z - x)$ yields

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n p_n = \rho^{-1}(x_n - z + \text{prox}_{\rho h}(z - x_n)) \\
 w_n = \text{prox}_{\gamma_n f}(x_n - \gamma_n p_n) \\
 x_{n+1} = x_n + \mu_n(w_n - x_n).\n\end{cases}
$$
\n(8.71)

It follows from Proposition [8.28](#page-90-4) that $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point x such that $(x, prox_{oh}(z - x))$ solves [\(8.69\)](#page-91-2).

Next, we revisit the problem of projecting onto the Minkowski sum of two convex sets (see Example [8.15\)](#page-86-1).

Example 8.33. Let C and D be nonempty closed convex subsets of H such that $C + D$ is closed, and let $z \in \mathcal{H}$. Upon setting $f = \iota_C$, $h = \iota_D$ and $\rho = 1$ in Example [8.32,](#page-91-4) (8.69) specializes to the problem of finding the projection of z onto $C + D$. Now let $x_0 \in C$, let $\varepsilon \in [0, 1/2]$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, 2 - \varepsilon]$, and let $(\mu_n)_{n \in \mathbb{N}}$ be a sequence in [ε , 1]. Then [\(8.71\)](#page-91-5) assumes the form

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n p_n = x_n - z + \text{proj}_D(z - x_n) \\
 w_n = \text{proj}_C(x_n - \gamma_n p_n) \\
 x_{n+1} = x_n + \mu_n (w_n - x_n),\n\end{cases}
$$
\n(8.72)

and it follows from Proposition [8.28](#page-90-4) that $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point x such that $proj_{C+D} z = x + proj_D(z-x)$. This best approximation algorithm was first obtained in [Seeger](#page-142-1) [\(1998,](#page-142-1) Theorem 2.1) in the case when ($\forall n \in \mathbb{N}$) $\gamma_n = \mu_n = 1$, that is,

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = \text{proj}_C(z - \text{proj}_D(z - x_n)). \tag{8.73}
$$

8.4.4. Dual implementation

We present a framework for solving strongly monotone composite inclusion problems by applying the forward–backward algorithm to the dual problem. The embedding underlying this approach is that of Example [3.22.](#page-29-0)

Problem 8.34. Let $\rho \in]0, +\infty[$, let $0 < p \in \mathbb{N}$, let $z \in \mathcal{H}$, and let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone. For every $k \in \{1, ..., p\}$, let $B_k: \mathcal{G}_k \to 2^{\mathcal{G}_k}$ be maximally monotone, let $v_k \in [0, +\infty[$, let $D_k: \mathcal{G}_k \to 2^{\mathcal{G}_k}$ be maximally monotone and v_k -strongly monotone, and suppose that $0 \neq L_k \in \mathcal{B}(\mathcal{H}, \mathcal{G}_k)$. Further, suppose that

$$
z \in \operatorname{ran}\left(A + \sum_{k=1}^{p} L_k^* \circ (B_k \square D_k) \circ L_k + \rho \operatorname{Id}\right). \tag{8.74}
$$

The problem is to solve the primal inclusion

find
$$
x \in \mathcal{H}
$$
 such that $z \in Ax + \sum_{k=1}^{p} L_k^*((B_k \square D_k)(L_k x)) + \rho x,$ (8.75)

together with the dual inclusion

find
$$
y_1^* \in G_1, ..., y_p^* \in G_p
$$
 such that $(\forall k \in \{1, ..., p\})$
\n
$$
0 \in -L_k \left(J_{A/\rho} \left(\frac{1}{\rho} \left(z - \sum_{j=1}^p L_j^* y_j^* \right) \right) \right) + B_k^{-1} y_k^* + D_k^{-1} y_k^*.
$$
\n(8.76)

We refer to Combettes and V \tilde{u} [\(2014,](#page-133-5) Proposition 5.2(iv)) for sufficient conditions that guarantee [\(8.74\)](#page-92-0). The mechanism to solve [\(8.75\)](#page-92-1) dually hinges on the following properties.

Proposition 8.35 (Combettes and Vũ [2014\)](#page-133-5). Consider the setting of Problem [8.34,](#page-92-2) and set

$$
M = A + \sum_{k=1}^{p} L_k^* \circ (B_k \square D_k) \circ L_k \quad \text{and} \quad \bar{x} = J_{M/\rho}(z/\rho). \tag{8.77}
$$

Then the following hold:

- (i) \bar{x} is the unique solution to the primal problem [\(8.75\)](#page-92-1).
- (ii) The dual problem [\(8.76\)](#page-92-3) admits solutions and, if $(\bar{y}_k^*)_{1 \leq k \leq p}$ solves (8.76), then

$$
\overline{x} = J_{A/\rho} \left(\rho^{-1} \left(z - \sum_{k=1}^{p} L_k^* \overline{y}_k^* \right) \right). \tag{8.78}
$$

We now apply the forward–backward algorithm of Theorem [8.1](#page-78-6) to the dual inclu-sion [\(8.76\)](#page-92-3) to construct a sequence $(x_n)_{n\in\mathbb{N}}$ which converges strongly to the solution to primal inclusion [\(8.75\)](#page-92-1). The following result is an adaptation of Corollary 5.4 of Combettes and Vũ [\(2014\)](#page-133-5).

Proposition 8.36. Consider the setting of Problem [8.34,](#page-92-2) and set

$$
\nu = \min_{1 \le k \le p} \nu_k \quad \text{and} \quad \alpha = \frac{1}{1/\nu + (1/\rho)\sum_{1 \le k \le p} ||L_k||^2}.
$$
 (8.79)

Let $\varepsilon \in [0, \alpha/(\alpha+1)]$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (2-\varepsilon)\alpha]$, suppose that $(\mu_n)_{n \in \mathbb{N}}$ satisfies [\(8.2\)](#page-78-0), and, for every $k \in \{1, ..., p\}$, let $y_{k,0}^* \in \mathcal{G}_k$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nq_n = z - \sum_{k=1}^p L_k^* y_{k,n}^* \\
x_n = J_{A/\rho}(q_n/\rho) \\
\text{for } k = 1, ..., p \\
w_{k,n} = y_{k,n}^* + \gamma_n (L_k x_n - D_k^{-1} y_{k,n}^*) \\
y_{k,n+1}^* = y_{k,n}^* + \mu_n (J_{\gamma_n B_k^{-1}} w_{k,n} - y_{k,n}^*).\n\end{cases}
$$
\n(8.80)

Then the following hold for the solution \bar{x} to [\(8.75\)](#page-92-1) and for some solution $\bar{y}^* =$ (\overline{y}_1^*) $j_1^*, \ldots, \overline{y}_p^*$) to [\(8.76\)](#page-92-3):

- (i) $(\forall k \in \{1, ..., p\})$ $y_{k,n}^* \rightarrow \overline{y}_k^*$.
- (ii) $x_n \to \overline{x}$.

Proof. We deduce from [Bauschke and Combettes](#page-127-1) [\(2017,](#page-127-1) Proposition 22.11(ii)) that, for every $k \in \{1, ..., p\}$, D_k^{-1} is v_k -cocoercive with dom $D_k^{-1} = \mathcal{G}_k$. Let us

set $\mathcal{G} = \mathcal{G}_1 \oplus \cdots \oplus \mathcal{G}_p$ and

$$
\begin{cases}\nT: \mathcal{H} \to \mathcal{H}: x \mapsto J_{\rho^{-1}A}(\rho^{-1}(z-x)), \\
A: \mathcal{G} \to 2^{\mathcal{G}}: y^* \mapsto \bigtimes_{1 \le k \le p} B_k^{-1} y_k^*, \\
D: \mathcal{G} \to \mathcal{G}: y^* \mapsto (D_k^{-1} y_k^*)_{1 \le k \le p}, \\
L: \mathcal{H} \to \mathcal{G}: x \mapsto (L_k x)_{1 \le k \le p}, \\
B = D - L \circ T \circ L^*.\n\end{cases} \tag{8.81}
$$

It follows from Lemmas [2.23](#page-16-0) and [2.24](#page-16-1) that \vec{A} is maximally monotone, from [\(8.79\)](#page-93-0) that **D** is v-cocoercive, from Lemma [2.34\(](#page-20-3)[iii\)](#page-20-4) that $-T$ is ρ -cocoercive, and hence from [Bauschke and Combettes](#page-127-1) [\(2017,](#page-127-1) Proposition 4.12) that

$$
B = D + L \circ (-T) \circ L^* \text{ is } 1/(1/\nu + ||L||^2/\rho)\text{-cocoercive.}
$$
 (8.82)

Since $||L||^2 \le \sum_{k=1}^p ||L_k||^2$, [\(8.79\)](#page-93-0) implies that **B** is α -cocoercive. Next, let us define (∀*n* ∈ ℕ) $y_n^* = (y_{k,n}^*)_{1 \le k \le p}$ and $w_n = (w_{k,n})_{1 \le k \le p}$. Then, upon combining (8.81) and Example [2.37,](#page-20-2) (8.80) can be rewritten as

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n w_n = y_n^* - \gamma_n B y_n^* \\
 y_{n+1}^* = y_n^* + \mu_n (J_{\gamma_n A} w_n - y_n^*),\n\end{cases}
$$
\n(8.83)

and the dual problem [\(8.76\)](#page-92-3) as

find
$$
y^* \in \mathcal{G}
$$
 such that $0 \in Ay^* + By^*$. (8.84)

- [\(i\)](#page-93-2) In view of the above, the claim follows from Theorem [8.1\(](#page-78-6)[i\)](#page-78-2).
- [\(ii\)](#page-93-3) We derive from Proposition [8.35,](#page-93-4) [\(8.80\)](#page-93-1) and [\(8.81\)](#page-94-0) that

$$
\overline{x} = T(L^*\overline{y}^*) \quad \text{and} \quad (\forall n \in \mathbb{N}) \quad x_n = T(L^*y_n^*). \tag{8.85}
$$

In turn, we deduce from the ρ -cocoercivity of $-T$, [\(i\)](#page-93-2), the monotonicity of D , and the Cauchy–Schwarz inequality that

$$
(\forall n \in \mathbb{N}) \quad \rho ||x_n - \overline{x}||^2 = \rho ||T(L^*y_n^*) - T(L^*\overline{y}^*)||^2
$$

\n
$$
\leq \langle L^*(y_n^* - \overline{y}^*) | T(L^*\overline{y}^*) - T(L^*y_n^*) \rangle
$$

\n
$$
= \langle y_n^* - \overline{y}^* | (L \circ T \circ L^*)\overline{y}^* - (L \circ T \circ L^*)y_n^* \rangle
$$

\n
$$
\leq \langle y_n^* - \overline{y}^* | Dy_n^* - Dy^* \rangle
$$

\n
$$
- \langle y_n^* - \overline{y}^* | (L \circ T \circ L^*)y_n^* - (L \circ T \circ L^*)\overline{y}^* \rangle
$$

\n
$$
= \langle y_n^* - \overline{y}^* | By_n^* - B\overline{y}^* \rangle
$$

\n
$$
\leq \delta ||By_n^* - B\overline{y}^*||, \qquad (8.86)
$$

where, by [\(i\)](#page-93-2),

$$
\delta = \sup_{n \in \mathbb{N}} \| \mathbf{y}_n^* - \overline{\mathbf{y}}^* \| < +\infty. \tag{8.87}
$$

Therefore, using [\(8.83\)](#page-94-1) and Theorem [8.1](#page-78-6)[\(ii\)](#page-78-3)–[\(iii\)](#page-78-5), we conclude that $||x_n - \overline{x}|| \to 0$. \Box

Here is an application to strongly convex minimization problems that arise in particular in mechanics [\(Ekeland and Temam](#page-135-5) [1974,](#page-135-5) [Mercier](#page-139-1) [1980\)](#page-139-1) and in signal processing (Combettes, Dinh Dũng and Vũ [2010,](#page-133-6) [2011,](#page-133-7) [Potter and Arun](#page-140-4) [1993\)](#page-140-4).

Example 8.37. Let $0 < p \in \mathbb{N}$, let $z \in \mathcal{H}$, let $f \in \Gamma_0(\mathcal{H})$, and let $\Gamma(f^*)$ be the Moreau envelope of f^* (see [\(2.11\)](#page-6-1)). For every $k \in \{1, ..., p\}$, let $g_k \in \Gamma_0(\mathcal{G}_k)$, let $v_k \in [0, +\infty]$, let $h_k \in \Gamma_0(\mathcal{G}_k)$ be v_k -strongly convex, and suppose that $0 \neq L_k \in$ $\mathcal{B}(\mathcal{H}, \mathcal{G}_k)$. Define α as in [\(8.79\)](#page-93-0) and suppose that

$$
z \in \operatorname{ran}\left(\partial f + \sum_{k=1}^{p} L_k^* \circ (\partial g_k \Box \partial h_k) \circ L_k + \operatorname{Id}\right). \tag{8.88}
$$

Then the primal problem

$$
\underset{x \in \mathcal{H}}{\text{minimize}} \quad f(x) + \sum_{k=1}^{p} (g_k \Box h_k)(L_k x) + \frac{1}{2} ||x - z||^2 \tag{8.89}
$$

admits a unique solution \bar{x} , namely

$$
\overline{x} = \text{prox}_{f + \sum_{k=1}^{P} (g_k \Box h_k) \circ L_k} z,
$$
\n(8.90)

and the dual problem is

$$
\underset{\mathbf{y}_1^* \in \mathcal{G}_1, \dots, \mathbf{y}_p^* \in \mathcal{G}_p}{\text{minimize}} \quad {}^1(f^*) \bigg(z - \sum_{k=1}^p L_k^* \mathbf{y}_k^* \bigg) + \sum_{k=1}^p (g_k^*(\mathbf{y}_k^*) + h_k^*(\mathbf{y}_k^*)). \tag{8.91}
$$

Now let $\varepsilon \in [0, \alpha/(\alpha+1)]$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (2-\varepsilon)\alpha]$, suppose that $(\mu_n)_{n \in \mathbb{N}}$ satisfies [\(8.2\)](#page-78-0), and, for every $k \in \{1, ..., p\}$, let $y_{k,0}^* \in \mathcal{G}_k$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nq_n = z - \sum_{k=1}^p L_k^* y_{k,n}^* \\
x_n = \text{prox}_f q_n \\
\text{for } k = 1, ..., p \\
w_{k,n} = y_{k,n}^* + \gamma_n (L_k x_n - \nabla h_k^* (y_{k,n}^*)) \\
y_{k,n+1}^* = y_{k,n}^* + \mu_n (\text{prox}_{\gamma_n g_k^*} w_{k,n} - y_{k,n}^*)\n\end{cases}
$$
\n(8.92)

Then the following hold:

- (i) There exists a solution (\bar{y}_1^*) $\{1, \ldots, \bar{y}_p^*\}\$ to [\(8.91\)](#page-95-0) such that $(\forall k \in \{1, \ldots, p\})$ $y_{k,n}^* \rightharpoonup \overline{y}_k^*.$
- (ii) $x_n \to \overline{x}$.

Proof. Apply Proposition [8.36](#page-93-5) with $\rho = 1$, $A = \partial f$, and $(\forall k \in \{1, ..., p\})$ $B_k = \partial g_k$ and $D_k = \partial h_k$; see Combettes and Vũ [\(2014,](#page-133-5) Example 5.6) for details. \Box

Remark 8.38. In Example [8.37,](#page-95-1) suppose that $\mathcal{H} = H_0^1(\Omega)$, where Ω is a bounded open domain in \mathbb{R}^2 , $p = 1$, $\mathcal{G}_1 = L^2(\Omega) \oplus L^2(\Omega)$, $L_1 = \nabla$, $g_1 = \mu \| \cdot \|_{2,1}$ with $\mu \in]0, +\infty[$, and $h_1 = \iota_{\{0\}}$. Then [\(8.89\)](#page-95-2) reduces to

minimize
$$
f(x) + \mu \int_{\Omega} |\nabla x(\omega)|_2 d\omega + \frac{1}{2} ||x - z||^2
$$
. (8.93)

In mechanics, (8.93) has been studied for certain potentials f [\(Ekeland and Temam](#page-135-5) [1974\)](#page-135-5). For instance, $f = 0$ yields Mossolov's problem and its dual analysis is carried out in [Ekeland and Temam](#page-135-5) [\(1974,](#page-135-5) Section IV.3.1). In image processing, Mossolov's problem corresponds to the total variation denoising problem. [Mercier](#page-139-1) [\(1980\)](#page-139-1) proposed a dual projection algorithm to solve Mossolov's problem. In image processing, this approach was rediscovered in a discrete setting in[Chambolle](#page-131-5) [\(2004,](#page-131-5) [2005\)](#page-131-6).

8.4.5. Barycentric Dykstra-like algorithm

Using Proposition [8.36](#page-93-5) and, thereby, the forward–backward algorithm, we obtain a method for computing the resolvent of a sum of maximally monotone operators. This result, which generalizes the barycentric Dykstra algorithm of [Gaffke](#page-135-6) [and Mathar](#page-135-6) [\(1989\)](#page-135-6) for projecting onto an intersection of closed convex sets, was originally derived in [Combettes](#page-132-6) [\(2009,](#page-132-6) Theorem 3.3) with different techniques.

Proposition 8.39. Let $0 < p \in \mathbb{N}$, let $z \in \mathcal{H}$, and, for every $k \in \{1, ..., p\}$, let $A_k: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone. Suppose that

$$
z \in \operatorname{ran}\left(\sum_{k=1}^{P} A_k + \operatorname{Id}\right) \tag{8.94}
$$

and consider the inclusion problem

find
$$
x \in \mathcal{H}
$$
 such that $z \in \sum_{k=1}^{p} A_k x + x$. (8.95)

Set $x_0 = z$ and $(\forall k \in \{1, ..., p\})$ $z_{k,0} = z$. Iterate

Ī

for
$$
n = 0, 1, ...
$$

\nfor $k = 1, ..., p$
\n
$$
\begin{cases}\nr_{k,n} = J_{pA_k} z_{k,n} \\
x_{n+1} = (1/p) \sum_{k=1}^p r_{k,n} \\
for $k = 1, ..., p$ \n
$$
\begin{cases}\nx_{k,n+1} = z_{k,n} - r_{k,n} + x_{n+1}.\n\end{cases}
$$
\n(8.96)
$$

Then $x_n \to J_{\sum_{k=1}^p A_k} z$.

Proof. First, we observe that (8.94) – (8.95) is the special case of (8.74) – (8.75) in which $A = 0$ and, for every $k \in \{1, \ldots, p\}$, $\mathcal{G}_k = \mathcal{H}$, $B_k = A_k$, $L_k = \text{Id}$ and $D_k = \{0\}^{-1}$. Moreover, the cocoercivity constant in [\(8.79\)](#page-93-0) is $\alpha = 1/p$. With this scenario, implementing [\(8.80\)](#page-93-1) with, for every $n \in \mathbb{N}$, $\mu_n = 1$ and $\gamma_n = 1/p$, and, for every $k \in \{1, ..., p\}$, $y_{k,0}^* = 0$ leads to the recursion

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nx_n = z - \sum_{k=1}^p y_{k,n}^* \\
\text{for } k = 1, ..., p \\
y_{k,n+1}^* = J_{A_k^{-1}/p}(y_{k,n}^* + x_n/p),\n\end{cases}
$$
\n(8.97)

and Proposition [8.36](#page-93-5)[\(ii\)](#page-93-3) guarantees that $x_n \to J_{\sum_{k=1}^p A_k}$ \bar{z} . Alternatively, with the initialization $x_0 = z$, we rewrite [\(8.97\)](#page-97-0) as

for
$$
n = 0, 1, ...
$$

\nfor $k = 1, ..., p$
\n
$$
\begin{cases}\ny_{k,n+1}^* = J_{A_k^{-1}/p}(y_{k,n}^* + x_n/p) \\
x_{n+1} = z - \sum_{k=1}^p y_{k,n+1}^*.\n\end{cases}
$$
\n(8.98)

Let us introduce the variables $(\forall n \in \mathbb{N})(\forall k \in \{1, ..., p\})$ $z_{k,n} = py_{k,n}^* + x_n$, where $z_{k,0} = x_0 = z$. Then [\(8.98\)](#page-97-1) corresponds to the iterations

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n x_{n+1} = z - \sum_{k=1}^{p} J_{A_k^{-1}/p}(z_{k,n}/p) \\
 \text{for } k = 1, ..., p \\
 \sum_{k=1}^{p} z_{k,n+1} = p J_{A_k^{-1}/p}(z_{k,n}/p) + x_{n+1}.\n\end{cases}
$$
\n(8.99)

By construction,

$$
(\forall n \in \mathbb{N}) \quad \sum_{k=1}^{p} z_{k,n} = pz. \tag{8.100}
$$

Hence, appealing to [\(2.21\)](#page-7-2), [\(8.99\)](#page-97-2) becomes

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nx_{n+1} = (1/p) \sum_{k=1}^{p} J_{pA_k} z_{k,n} \\
\text{for } k = 1, ..., p \\
z_{k,n+1} = z_{k,n} - J_{pA_k} z_{k,n} + x_{n+1},\n\end{cases}
$$
\n(8.101)

 \Box

which is precisely [\(8.96\)](#page-96-3).

Example 8.40. Consider the instantiation of Proposition [8.39](#page-96-4) in which, for every $k \in \{1, \ldots, p\}, A_k = \partial f_k$, with $f_k \in \Gamma_0(\mathcal{H})$, and execute [\(8.96\)](#page-96-3), which becomes

for
$$
n = 0, 1, ...
$$

\nfor $k = 1, ..., p$
\n
$$
\begin{cases}\nr_{k,n} = \text{prox}_{p\hat{f}_k} z_{k,n} \\
x_{n+1} = (1/p) \sum_{k=1}^p r_{k,n} \\
\text{for } k = 1, ..., p \\
z_{k,n+1} = z_{k,n} - r_{k,n} + x_{n+1}.\n\end{cases}
$$
\n(8.102)

Then $x_n \to \text{prox}_{\sum_{k=1}^p f_k}$ z.

Our last example addresses the barycentric Dykstra algorithm *per se*. The original Dykstra algorithm was devised in [Dykstra](#page-134-4) [\(1983\)](#page-134-4) to project onto the intersection of closed convex cones (see also [Han](#page-136-3) [1988](#page-136-3) for general closed convex sets whose intersection has a nonempty interior) in Euclidean spaces using periodic applications of the projectors onto the individual sets. Convergence of this periodic scheme in the general case of arbitrary closed and convex sets in Hilbert spaces was established in [Boyle and Dykstra](#page-129-1) [\(1986\)](#page-129-1); see [Bauschke and Combettes](#page-127-4) [\(2008\)](#page-127-4) for an extension to monotone operators. The barycentric version described below, in which all the projectors are used at each iteration, was devised in [Gaffke and](#page-135-6) [Mathar](#page-135-6) [\(1989,](#page-135-6) Section 6). Its connection with the forward–backward algorithm is discussed in [Combettes](#page-133-6) *et al.* [\(2010,](#page-133-6) Remark 3.8) and [Combettes](#page-133-7) *et al.* [\(2011,](#page-133-7) Remark 2.3), and its asymptotic behaviour in the inconsistent case in [Bauschke and](#page-127-5) [Borwein](#page-127-5) [\(1994,](#page-127-5) Theorem 6.1).

Example 8.41. In Example [8.40,](#page-98-0) suppose that, for every $k \in \{1, \ldots, p\}$, $f_k =$ ι_{C_k} , where C_k is a nonempty closed convex subset of H. Then algorithm [\(8.102\)](#page-98-1) becomes

for
$$
n = 0, 1, ...
$$

\nfor $k = 1, ..., p$
\n
$$
\begin{cases}\nr_{k,n} = \text{proj}_{C_k} z_{k,n} \\
x_{n+1} = (1/p) \sum_{k=1}^p r_{k,n} \\
\text{for } k = 1, ..., p \\
z_{k,n+1} = z_{k,n} - r_{k,n} + x_{n+1},\n\end{cases}
$$
\n(8.103)

and $x_n \to \text{proj}_{\bigcap_{k=1}^p} C_k$ z.

8.4.6. Renorming

We preface our discussion with a renormed version of Theorem [8.1.](#page-78-6)

Ī

Proposition 8.42. Let $\alpha \in]0, +\infty[$, let $\beta \in]0, +\infty[$, let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, let $B: H \to H$ be α -cocoercive, let $U \in B(H)$ be self-adjoint and β -strongly monotone, and let X be the real Hilbert space obtained by endowing H with the scalar product $(x, y) \mapsto \langle Ux | y \rangle$. Let $\varepsilon \in [0, \alpha \beta/(\alpha \beta + 1)]$, let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (2 - \varepsilon)\alpha\beta]$, and let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, 1]$. Suppose that the set Z of solutions to the problem

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + Bx$ (8.104)

is not empty and let Z^* be the set of solutions to the dual problem

find
$$
x^* \in \mathcal{H}
$$
 such that $0 \in -A^{-1}(-x^*) + B^{-1}x^*$. (8.105)

Let $x_0 \in \mathcal{H}$ and iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n u_n^* = \gamma_n^{-1} U x_n - B x_n \\
 w_n = (\gamma_n^{-1} U + A)^{-1} u_n^* \\
 x_{n+1} = x_n + \lambda_n (w_n - x_n).\n\end{cases}
$$
\n(8.106)

Then the following hold:

- (i) $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z.
- (ii) Z^* contains a single point \overline{x}^* and $(\forall z \in Z)$ $Bz = \overline{x}^*$.
- (iii) $(Bx_n)_{n \in \mathbb{N}}$ converges strongly to \overline{x}^* .

Proof. We derive from Lemma [2.25](#page-16-2) and Example [2.39](#page-20-5) that

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n + \lambda_n \left(J_{\gamma_n U^{-1} \circ A} \left(x_n - \gamma_n U^{-1} (B x_n) \right) - x_n \right), \tag{8.107}
$$

where $U^{-1} \circ A: \mathcal{X} \to 2^{\mathcal{X}}$ is maximally monotone, $U^{-1} \circ B: \mathcal{X} \to \mathcal{X}$ is $\alpha \beta$ cocoercive, and $zer(A + B) = zer(U^{-1} \circ (A + B))$. Hence the assertions follow from Theorem [8.1](#page-78-6) applied to $U^{-1} \circ A$ and $U^{-1} \circ B$ in \mathcal{X} . П

Remark 8.43. In terms of the warped resolvents of Section [2.4.3,](#page-21-0) [\(8.106\)](#page-99-0) can be condensed into

$$
(\forall n \in \mathbb{N}) \quad x_{n+1} = x_n + \lambda_n \left(J_{\gamma_n(A+B)}^{U_n} x_n - x_n \right), \quad \text{where } U_n = U - \gamma_n B. \tag{8.108}
$$

We present an approach proposed in $V\tilde{u}$ [\(2013\)](#page-144-2), which revisited the primal– dual setting of [Combettes and Pesquet](#page-133-0) [\(2012\)](#page-133-0) discussed in Proposition [7.10](#page-74-3) by replacing the monotone Lipschitz property of the operators C and $(D_k^{-1})_{1 \leq k \leq p}$ with the stronger cocoercivity property.

Proposition 8.44 (V \tilde{u} **[2013\)](#page-144-2).** Let $0 < p \in \mathbb{N}$, let $\alpha \in (0, +\infty)$, let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, and let $C: \mathcal{H} \to \mathcal{H}$ be α -cocoercive. For every $k \in$ $\{1,\ldots,p\}$, let $\beta_k \in]0,+\infty[$, let \mathcal{G}_k be a real Hilbert space, let $B_k: \mathcal{G}_k \to 2^{\mathcal{G}_k}$ be maximally monotone, let $D_k: \mathcal{G}_k \to 2^{\mathcal{G}_k}$ be maximally monotone and β_k -strongly monotone, and suppose that $0 \neq L_k \in \mathcal{B}(\mathcal{H}, \mathcal{G}_k)$. Additionally, suppose that the set Z of solutions to the primal inclusion

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + \sum_{k=1}^{p} L_k^*((B_k \square D_k)(L_k x)) + Cx$ (8.109)

is not empty, and let Z^* be the set of solutions to the dual inclusion

find
$$
y_1^* \in \mathcal{G}_1, ..., y_p^* \in \mathcal{G}_p
$$
 such that
\n
$$
(\exists x \in \mathcal{H}) \begin{cases} x \in (A+C)^{-1} \left(-\sum_{k=1}^p L_k^* y_k^* \right), \\ (\forall k \in \{1, ..., p\}) \ L_k x \in B_k^{-1} y_k^* + D_k^{-1} y_k^* . \end{cases}
$$
\n(8.110)

Let $\varepsilon \in]0,1[$, let $(\lambda_n)_{n\in\mathbb{N}}$ be a sequence in $[\varepsilon, 1]$, let $x_0 \in \mathcal{H}$, let $(y_{1,0}^*, \ldots, y_{p,0}^*) \in$ $\mathcal{G}_1 \oplus \cdots \oplus \mathcal{G}_p$, let $\tau \in]0, +\infty[$, and let $(\sigma_1, \ldots, \sigma_p) \in]0, +\infty[^p$. Set

$$
\mathbf{N} = \min\{\alpha, \beta_1, \dots, \beta_p\} \quad \text{and} \quad \beta = \frac{1 - \sqrt{\tau \sum_{k=1}^p \sigma_k ||L_k||^2}}{\max\{\tau, \sigma_1, \dots, \sigma_p\}} \tag{8.111}
$$

and assume that

$$
\aleph \beta > \frac{1}{2}.\tag{8.112}
$$

Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nx_n^* = \tau \left(\sum_{k=1}^p L_k^* y_{k,n}^* + Cx_n \right) \\
p_n = J_{\tau A}(x_n - x_n^*) \\
x_{n+1} = x_n + \lambda_n (p_n - x_n) \\
\text{for } k = 1, ..., p \\
y_{k,n} = \sigma_k \left(L_k (2p_n - x_n) - D_k^{-1} y_{k,n}^* \right) \\
q_{k,n}^* = J_{\sigma_k B_k^{-1}} (y_{k,n}^* + y_{k,n}) \\
y_{k,n+1}^* = y_{k,n}^* + \lambda_n \left(q_{k,n}^* - y_{k,n}^* \right).\n\end{cases}
$$
\n(8.113)

Then there exist $x \in Z$ and (y_1^*) $\chi_1^*, \ldots, \chi_p^* \in Z^*$ such that $x_n \to x$, and, for every $k \in \{1, ..., p\}, y_{k,n}^* \to y_k^*.$

Proof. Set $X = H \oplus G_1 \oplus \cdots \oplus G_p$ and

$$
\begin{cases}\nM: \mathbf{X} \to 2^{\mathbf{X}}: (x, y_1^*, \dots, y_p^*) \mapsto \\
(Ax + \sum_{k=1}^p L_k^* y_k^*) \times (-L_1 x + B_1^{-1} y_1^*) \times \dots \times (-L_p x + B_p^{-1} y_p^*), \\
C: \mathbf{X} \to \mathbf{X}: (x, y_1^*, \dots, y_p^*) \mapsto (Cx, D_1^{-1} y_1^*, \dots, D_p^{-1} y_p^*), \\
U: \mathbf{X} \to \mathbf{X}: (x, y_1^*, \dots, y_p^*) \mapsto \\
(\tau^{-1} x - \sum_{k=1}^p L_k^* y_k^*, -L_1 x + \sigma_1^{-1} y_1^*, \dots, -L_p x + \sigma_p^{-1} y_p^*).\n\end{cases} (8.114)
$$

As in [\(5.61\)](#page-56-0), M is maximally monotone, while C is \aleph -cocoercive. Furthermore, $U \in \mathcal{B}(\mathcal{H})$ is self-adjoint and, as shown in Vũ [\(2013,](#page-144-2) equation (3.20)), [\(8.112\)](#page-100-0) implies that it is β -strongly monotone. Now set ($\forall n \in \mathbb{N}$) $x_n = (x_n, y_{1,n}^*, \dots, y_{p,n}^*)$ and $w_n = (p_n, q_{1,n}^*, \ldots, q_{p,n}^*)$. Then, adopting the same pattern as in the proof of

Example [5.20,](#page-55-0) we rewrite [\(8.113\)](#page-100-1) as

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\n u_n^* = Ux_n - Cx_n \\
 w_n = (U + M)^{-1}u_n^* \\
 x_{n+1} = x_n + \lambda_n(w_n - x_n),\n\end{cases}
$$
\n(8.115)

and thus recover [\(8.106\)](#page-99-0) with $(\forall n \in \mathbb{N})$ $\gamma_n = 1 < 2\aleph \beta$. We therefore ap-peal to Proposition [8.42\(](#page-98-2)[i\)](#page-99-1) to obtain the weak convergence of $(x_n)_{n \in \mathbb{N}}$ to a point $(x, y_1^*, \ldots, y_p^*) \in \text{zer}(M + C)$. However, replacing A with $A + C$ and $(B_k^{-1})_{1 \leq k \leq p}$ with $(B_k^{-1} + D_k^{-1})_{1 \le k \le p}$ in Lemma [3.12\(](#page-26-1)[ii\)](#page-26-2) yields zer($M + C$) $\subset Z \times Z^*$. \Box

Remark 8.45. In terms of Framework [1.2,](#page-4-0) the embedding underlying Propos-ition [8.44](#page-99-2) employs $X = H \oplus G_1 \oplus \cdots \oplus G_p$, $M = M + C$ and $T: X \rightarrow$ $\mathcal{H}: (x, y_1^*, \ldots, y_p^*) \mapsto x.$

The following application to minimization revisits the setting of Example [7.13](#page-76-2) and Remark [7.14.](#page-77-1)

Example 8.46. Let $0 < p \in \mathbb{N}$, let $\alpha \in [0, +\infty)$, let $f \in \Gamma_0(\mathcal{H})$, and let $h: \mathcal{H} \to$ R be convex, differentiable, and such that ∇h is $1/\alpha$ -Lipschitzian. For every $k \in \{1, \ldots, p\}$, let $\beta_k \in [0, +\infty)$, let \mathcal{G}_k be a real Hilbert space, let $g_k \in \Gamma_0(\mathcal{G}_k)$, let $\ell_k \in \Gamma_0(\mathcal{G}_k)$ be β_k -strongly convex, and suppose that $0 \neq L_k \in \mathcal{B}(\mathcal{H}, \mathcal{G}_k)$. Let Z be the set of solutions to the primal problem

minimize
$$
f(x) + \sum_{k=1}^{p} (g_k \Box \ell_k)(L_k x) + h(x),
$$
 (8.116)

let Z^* be the set of solutions to the dual problem

$$
\underset{y_1^* \in \mathcal{G}_1, \dots, y_p^* \in \mathcal{G}_p}{\text{minimize}} \quad (f^* \sqcup h^*) \bigg(-\sum_{k=1}^p L_k^* y_k^* \bigg) + \sum_{k=1}^p (g_k^* (y_k^*) + \ell_k^* (y_k^*)),\tag{8.117}
$$

and suppose that

$$
\operatorname{zer}\left(\partial f + \sum_{k=1}^p L_k^* \circ (\partial g_k \Box \partial \ell_k) \circ L_k + \nabla h\right) \neq \emptyset. \tag{8.118}
$$

Let $\varepsilon \in]0,1[$, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, 1]$, let $x_0 \in \mathcal{H}$, let $(y_{1,0}^*, \ldots, y_{p,0}^*) \in$ $\mathcal{G}_1 \oplus \cdots \oplus \mathcal{G}_p$, let $\tau \in]0, +\infty[$, and let $(\sigma_1, \ldots, \sigma_p) \in]0, +\infty[$ ^p be such that

[\(8.111\)](#page-100-2)–[\(8.112\)](#page-100-0) hold. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nx_n^* = \tau \left(\sum_{k=1}^p L_k^* y_{k,n}^* + \nabla h(x_n) \right) \\
p_n = \text{prox}_{\tau f} (x_n - x_n^*) \\
x_{n+1} = x_n + \lambda_n (p_n - x_n) \\
\text{for } k = 1, ..., p \\
y_{k,n} = \sigma_k \left(L_k (2p_n - x_n) - \nabla \ell_k^* (y_{k,n}^*) \right) \\
q_{k,n}^* = \text{prox}_{\sigma_k g_k^*} (y_{k,n}^* + y_{k,n}) \\
y_{k,n+1}^* = y_{k,n}^* + \lambda_n (q_{k,n}^* - y_{k,n}^*).\n\end{cases}
$$
\n(8.119)

Then there exist $x \in Z$ and (y_1^*) $\chi_1^*, \ldots, \chi_p^*$ $\in Z^*$ such that $x_n \to x$, and, for every $k \in \{1, ..., p\}, y_{k,n}^* \to y_k^*.$

Proof. It follows from the arguments presented in [Combettes and Pesquet](#page-133-0) [\(2012,](#page-133-0) Section 4) that this is an application of Proposition [8.44](#page-99-2) with $A = \partial f$, $C = \nabla h$, and $(\forall k \in \{1, ..., p\}) B_k = \partial g_k$ and $D_k = \partial \ell_k$. \Box

Remark 8.47. If we make the additional assumptions that, for every $k \in \{1, \ldots, p\}$, $\ell_k = \ell_{\{0\}}$ and $\sigma_k = \sigma_1$, Example [8.46](#page-101-0) was independently obtained in [Condat](#page-133-8) [\(2013,](#page-133-8) Section 5). For this reason, [\(8.119\)](#page-102-0) in this particular setting is called the *Condat*–Vuⁿ algorithm.

8.5. Forward–backward–half-forward splitting

Let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, let $C: \mathcal{H} \to \mathcal{H}$ be cocoercive, and let $Q: \mathcal{H} \to \mathcal{H}$ be monotone and Lipschitzian. Then a zero of $M = A + C + Q$ can be constructed through the forward–backward–forward algorithms of Theorem [7.1](#page-67-1) or Theorem [7.2,](#page-68-1) applied to A and the monotone and Lipschitzian operator $B = C + Q$. These algorithms require two applications of B , i.e. two applications of C and Q , at each iteration. However, the algorithms discussed so far require two applications of a monotone Lipschitzian operator per iteration, as in the Antipin–Korpelevič method of Section [7.1](#page-66-0) and the forward–backward–forward methods of Sections [7.2](#page-67-2) and [7.3,](#page-68-2) but only one application of a cocoercive operator, as in the Euler method of Section [5.4.1](#page-45-0) and the forward–backward methods of Sections [8.2](#page-78-8) and [8.3.](#page-83-4) It is therefore natural to ask whether one can find a zero of $A + C + O$ using only one application of C per iteration. A positive answer to this question was given in [Briceño-Arias and Davis](#page-130-1) [\(2018\)](#page-130-1) with the following forward–backward–halfforward splitting algorithm. We provide a simple proof of its convergence using our geometric framework.

Proposition 8.48 [\(Briceño-Arias and Davis](#page-130-1) [2018\)](#page-130-1). Let $\alpha \in [0, +\infty)$, let $\beta \in$]0, +∞[, let $A: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, let $C: \mathcal{H} \to \mathcal{H}$ be α -cocoercive, let $Q: \mathcal{H} \to \mathcal{H}$ be monotone and β -Lipschitzian, and suppose that the set of solutions Z to the inclusion

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + Cx + Qx$ (8.120)

is not empty. Let $x_0 \in \mathcal{H}$, set $\chi = 4\alpha/(1 + \sqrt{1 + 16\alpha^2 \beta^2})$, let $\varepsilon \in [0, \chi/(\chi + 1)]$, and let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (1 - \varepsilon)\chi]$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nc_n^* = \gamma_n C x_n \\
q_n^* = \gamma_n Q x_n \\
w_n = J_{\gamma_n} A(x_n - c_n^* - q_n^*) \\
x_{n+1} = w_n - \gamma_n Q w_n + q_n^*. \n\end{cases}
$$
\n(8.121)

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point in Z.

Proof. The claims will be established as an application of Theorem [4.12](#page-39-0) with

$$
W = A + Q, \quad \text{and} \quad (\forall n \in \mathbb{N}) \quad U_n = \gamma_n^{-1} \text{Id} - C - Q \quad \text{and} \quad q_n = x_n. \tag{8.122}
$$

In this setting, Proposition 3.9 of [Bùi and Combettes](#page-130-0) [\(2020](#page-130-0)*b*) implies that [\(7.5\)](#page-68-0) is satisfied, we have

$$
(\forall n \in \mathbb{N}) \quad J_{W+C}^{U_n} = (\gamma_n^{-1} \text{Id} + A) \circ (\gamma_n^{-1} \text{Id} - C - Q)
$$

$$
= J_{\gamma_n A} \circ (\text{Id} - \gamma_n (C + Q)), \tag{8.123}
$$

and the variables of [\(4.34\)](#page-39-1) become

$$
(\forall n \in \mathbb{N})
$$
\n
$$
\begin{cases}\n w_n = J_{\gamma_n A}(x_n - \gamma_n(Cx_n + Qx_n)), \\
 t_n^* = (\gamma_n^{-1} \text{Id} - Q)x_n - (\gamma_n^{-1} \text{Id} - Q)w_n, \\
 \delta_n = \left(\frac{1}{\gamma_n} - \frac{1}{4\alpha}\right) ||w_n - x_n||^2 - \langle w_n - x_n | Qw_n - Qx_n \rangle.\n\end{cases}
$$
\n(8.124)

Now set

$$
(\forall n \in \mathbb{N}) \quad \lambda_n = \begin{cases} \frac{\gamma_n ||t_n^*||^2}{\delta_n}, & \text{if } \delta_n > 0, \\ \varepsilon, & \text{otherwise,} \end{cases} \tag{8.125}
$$

and note that the assumptions yield

$$
\inf_{n \in \mathbb{N}} \lambda_n > 0 \quad \text{and} \quad \sup_{n \in \mathbb{N}} \lambda_n < 2. \tag{8.126}
$$

As a consequence of (8.124) and the properties of Q , we have

$$
(\forall n \in \mathbb{N}) \quad \delta_n \le 0 \Rightarrow \left(\frac{1}{\gamma_n} - \frac{1}{4\alpha} - \beta\right) ||w_n - x_n||^2 \le 0
$$

$$
\Leftrightarrow w_n = x_n
$$

$$
\Leftrightarrow t_n^* = 0.
$$
 (8.127)

Hence, [\(4.34\)](#page-39-1) yields

$$
(\forall n \in \mathbb{N}) \quad d_n = \frac{\gamma_n}{\lambda_n} t_n^* = \frac{1}{\lambda_n} (x_n - w_n + \gamma_n (Qw_n - Qx_n)). \tag{8.128}
$$

As a result, the sequence $(x_n)_{n\in\mathbb{N}}$ produced by [\(8.121\)](#page-103-1) coincides with that of [\(4.34\)](#page-39-1). Hence, by Theorem [4.12](#page-39-0)[\(i\)](#page-39-2) and [\(8.126\)](#page-103-2), $\sum_{n \in \mathbb{N}} ||d_n||^2 < +\infty$ which, in view of [\(8.128\)](#page-104-0), yields

$$
(\text{Id} - \gamma_n Q)w_n - (\text{Id} - \gamma_n Q)x_n \to 0. \tag{8.129}
$$

However, since $\chi \leq 1/\beta$, $(\gamma_n)_{n \in \mathbb{N}}$ lies in $[\varepsilon, (1 - \varepsilon)/\beta]$ and Lemma [2.48](#page-22-0)[\(i\)](#page-22-2) implies that the operators $(\text{Id} - \gamma_n Q)_{n \in \mathbb{N}}$ are ε -strongly monotone. Hence,

$$
(\forall n \in \mathbb{N}) \quad \varepsilon \left\| w_n - x_n \right\|^2 \le \langle w_n - x_n \mid (\text{Id} - \gamma_n Q) w_n - (\text{Id} - \gamma_n Q) x_n \rangle \quad (8.130)
$$

and, by the Cauchy–Schwarz inequality and [\(8.129\)](#page-104-1),

$$
||w_n - x_n|| \le \varepsilon^{-1} || (\text{Id} - \gamma_n Q) w_n - (\text{Id} - \gamma_n Q) x_n || \to 0. \tag{8.131}
$$

In turn, since C is $1/\alpha$ -Lipschitzian, these facts confirm that

$$
||U_n w_n - U_n x_n|| \le \gamma_n^{-1} || (\text{Id} - \gamma_n Q) w_n - (\text{Id} - \gamma_n Q) x_n || + ||C w_n - C x_n ||
$$

\n
$$
\le \varepsilon^{-1} || (\text{Id} - \gamma_n Q) w_n - (\text{Id} - \gamma_n Q) x_n || + \alpha^{-1} ||w_n - x_n ||
$$

\n
$$
\to 0. \tag{8.132}
$$

Thus, the assertion follows from Theorem [4.12](#page-39-0)[\(ii\)](#page-39-4) since its conditions [\(iib\)](#page-39-3) and [\(iic\)](#page-39-5) are fulfilled. П

Remark 8.49. We complement Proposition [8.48](#page-102-1) with a few commentaries.

- (i) Suppose that $C = 0$. Then, since α can be arbitrarily large, $\chi = 1/\beta$ and [\(8.121\)](#page-103-1) reverts to the forward–backward–forward algorithm [\(7.2\)](#page-67-0).
- (ii) Suppose that $Q = 0$. Then, since $\beta = 0$, $\chi = 2\alpha$ and [\(8.121\)](#page-103-1) becomes an unrelaxed version of forward–backward algorithm [\(8.5\)](#page-78-1).
- (iii) Using the geometric pattern of the proof given above, a strongly convergent version of the forward–backward–half-forward algorithm can be derived from Theorem [4.14.](#page-41-0)

As an illustration, we extend the Lagrangian approach of Proposition [7.5.](#page-71-3)

Example 8.50. Let $f \in \Gamma_0(\mathcal{H})$, $g \in \Gamma_0(\mathcal{G})$ and $L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$ be such that $0 \in$ $sri(L(\text{dom } f) - \text{dom } g)$. Let $\alpha \in [0, +\infty[$ and let $h: \mathcal{H} \to \mathbb{R}$ be convex and differentiable and such that ∇h is $1/\alpha$ -Lipschitzian. Suppose that the primal problem

$$
\underset{x \in \mathcal{H}}{\text{minimize}} \quad f(x) + g(Lx) + h(x) \tag{8.133}
$$

admits solutions and consider the dual problem

$$
\underset{v^* \in \mathcal{G}}{\text{minimize}} \ (f^* \Box h^*)(-L^*v^*) + g^*(v^*). \tag{8.134}
$$

Let $(x_0, y_0, v_0^*) \in \mathcal{H} \oplus \mathcal{G} \oplus \mathcal{G}$, set $\chi = 4\alpha/(1 + \sqrt{1 + 16\alpha^2(1 + ||L||^2)})$, let $\varepsilon \in$ $[0, \chi/(\chi+1)]$, and let $(\gamma_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, (1-\varepsilon)\chi]$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
c_n^* = \gamma_n \nabla h(x_n)
$$
\n
$$
q_{1,n}^* = \gamma_n L^* v_n^*
$$
\n
$$
q_{2,n}^* = -\gamma_n v_n^*
$$
\n
$$
q_{3,n}^* = \gamma_n (y_n - Lx_n)
$$
\n
$$
a_{1,n} = \text{prox}_{\gamma_n f} (x_n - c_n^* - q_{1,n}^*)
$$
\n
$$
a_{2,n} = \text{prox}_{\gamma_n g} (y_n - q_{2,n}^*)
$$
\n
$$
x_{n+1} = a_{1,n} + \gamma_n L^* q_{3,n}^*
$$
\n
$$
y_{n+1} = a_{2,n} - \gamma_n q_{3,n}^*
$$
\n
$$
v_{n+1}^* = v_n^* + \gamma_n (La_{1,n} - a_{2,n}).
$$
\n(8.135)

Then $(x_n)_{n \in \mathbb{N}}$ and $(v_n^*)_{n \in \mathbb{N}}$ converge weakly to solutions to [\(8.133\)](#page-104-2) and [\(8.134\)](#page-104-3), respectively.

Proof. We adapt the approach of Section [7.4.2.](#page-71-4) The saddle operator of [\(7.22\)](#page-71-2)– (7.23) becomes $S = A + C + Q$, where

$$
\begin{cases}\nA: (x, y, v^*) \mapsto \partial f(x) \times \partial g(y) \times \{0\}, \\
C: (x, y, v^*) \mapsto (\nabla h(x), 0, 0), \\
Q: (x, y, v^*) \mapsto (L^*v^*, -v^*, -Lx + y).\n\end{cases}
$$
\n(8.136)

J. As in Section [7.4.2,](#page-71-4) A is maximally monotone and Q is monotone and $\sqrt{1 + ||L||^2}$. Lipschitzian. Further, by virtue of Lemma [2.2,](#page-9-0) C is α -cocoercive. Now set $(\forall n \in \mathbb{N})$ $x_n = (x_n, y_n, v_n^*),$ $c_n^* = (c_n^*, 0, 0),$ $q_n^* = (q_{1,n}^*, q_{2,n}^*, q_{3,n}^*)$ and $w_n =$ $(a_{1,n}, a_{2,n}, v_n^* - q_{3,n}^*)$. Then [\(8.135\)](#page-105-0) assumes the form

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nc_n^* = \gamma_n C x_n \\
q_n^* = \gamma_n Q x_n \\
w_n = J_{\gamma_n A}(x_n - c_n^* - q_n^*) \\
x_{n+1} = w_n - \gamma_n Q w_n + q_n^*,\n\end{cases}
$$
\n(8.137)

which is [\(8.121\)](#page-103-1). Hence, by Proposition [8.48,](#page-102-1) $(x_n, y_n, v_n^*)_{n \in \mathbb{N}}$ converges weakly to a point $(x, y, v^*) \in \text{zer } S$. \Box

Remark 8.51. Let $\alpha \in]0, +\infty[$, let $A: \mathcal{H} \to 2^{\mathcal{H}}$ and $B: \mathcal{G} \to 2^{\mathcal{G}}$ be maximally monotone, let $C: \mathcal{H} \to \mathcal{H}$ be α -cocoercive, and let $0 \neq L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$. As in Remark [7.8,](#page-73-6) the saddle approach of Example [8.50](#page-104-4) has a natural extension to the problem of finding a zero of $A + L^* \circ B \circ L + C$ and the dual problem of finding a zero of $-L \circ (A + C)^{-1} \circ (-L^*) + B^{-1}$. In this setting, the saddle operator is

$$
\mathcal{S}: \quad \mathcal{H} \oplus \mathcal{G} \oplus \mathcal{G} \quad \to \quad 2^{\mathcal{H} \oplus \mathcal{G} \oplus \mathcal{G}} \quad (x, y, v^*) \quad \mapsto \quad (Ax + Cx + L^*v^*) \times (By - v^*) \times \{-Lx + y\}. \tag{8.138}
$$

Accordingly, it suffices to replace ∇h with C , prox $\nabla_{\gamma_n} f$ with $J_{\gamma_n} A$ and prox $\nabla_{\gamma_n} g$ with J_{γ_n} in [\(8.135\)](#page-105-0) to find primal–dual solutions.

9. Block-iterative Kuhn–Tucker projective splitting

9.1. Preview

Unlike the methods described so far, those described in this section were explicitly designed by employing the geometric principle of Theorem [4.2.](#page-30-1) The terminology *projective splitting* was coined in [Eckstein and Svaiter](#page-134-5) [\(2008\)](#page-134-5) in the context of an algorithm to solve Problem [3.1](#page-23-0) by choosing points in the graph of A and B to construct half-spaces containing an 'extended solution set'. In the language of Lemma [3.8,](#page-24-3) this set is actually the set of zeros of the Kuhn–Tucker operator [\(3.10\)](#page-25-0), which collapses to

$$
\text{zer } \mathcal{K} = \{ (x, x^*) \in \mathcal{H} \oplus \mathcal{H} \mid -x^* \in Ax \text{ and } x \in B^{-1}x^* \}. \tag{9.1}
$$

[Eckstein and Svaiter](#page-134-5) [\(2008\)](#page-134-5) initiated a fruitful line of work towards more complex monotone inclusions [\(Alotaibi, Combettes and Shahzad](#page-126-1) [2014,](#page-126-1) [2015,](#page-126-2) [Bednarczuk](#page-128-7) *[et al.](#page-128-7)* [2018,](#page-128-7) [Bùi](#page-130-2) [2022](#page-130-2)*b*, [Combettes and Eckstein](#page-132-7) [2018,](#page-132-7) [Eckstein](#page-134-6) [2017,](#page-134-6) [Eckstein](#page-134-7) [and Svaiter](#page-134-7) [2009,](#page-134-7) [Johnstone and Eckstein](#page-137-1) [2019,](#page-137-1) [2020,](#page-137-2) [2021,](#page-137-3) [2022,](#page-137-4) [Machado](#page-138-6) [2018,](#page-138-6) [Machado and Sicre](#page-138-7) [2023,](#page-138-7) [Sicre](#page-142-2) [2020\)](#page-142-2). We use the term *Kuhn–Tucker projective splitting* to describe a method that operates through the principles of Frame-work [1.2,](#page-4-0) where $\mathcal M$ is a Kuhn–Tucker operator. As we shall see, projective splitting algorithms have features quite different from those of the traditional methods of Sections [5–](#page-42-1)[8](#page-77-2) and they display an unprecedented level of flexibility in terms of implementation.

9.2. Primal–dual composite inclusions

Let us go back to the composite Problem [3.7.](#page-24-0) The sets of primal and dual solutions are, respectively,

$$
Z = \text{zer}(A + L^* \circ B \circ L) \quad \text{and} \quad Z^* = \text{zer}(-L \circ A^{-1} \circ (-L^*) + B^{-1}). \tag{9.2}
$$

Moreover, as pointed out in Example [3.20,](#page-29-1) an embedding of [\(3.7\)](#page-24-1) is $(X, \mathcal{K}, \mathcal{T})$, where $X = H \oplus G$, K is the Kuhn–Tucker operator of [\(3.10\)](#page-25-0), that is,

$$
\mathcal{K}: \mathbf{X} \to 2^{\mathbf{X}}: (x, y^*) \mapsto (Ax + L^*y^*) \times (B^{-1}y^* - Lx), \tag{9.3}
$$

and $\mathcal{T}: \mathbf{X} \to \mathcal{H}: (x, y^*) \mapsto x$. The task is therefore to find a zero of \mathcal{K} . This is the path followed in the monotone+skew approach of Section [7.4.1.](#page-69-0) However, this method requires knowledge of $||L||$ (or of a tight upper bound for it), which may be difficult to obtain in certain problems. The renormed algorithms of Example [5.20](#page-55-0) and [Boţ and Hendrich](#page-129-2) [\(2013\)](#page-129-2), the saddle algorithm of Remark [8.51](#page-105-1) and the minimal lifting algorithm of [Aragón-Artacho](#page-126-3) *et al.* [\(2023\)](#page-126-3) share the same potential limitation. On the other hand, the method of Proposition [5.15,](#page-51-0) which was derived from the method of partial inverses, requires the inversion of linear operators, a task that may also face implementation issues.

A strategy which circumvents the above shortcomings was proposed in [Alotaibi](#page-126-1) *[et al.](#page-126-1)* [\(2014\)](#page-126-1), where the approach of [Eckstein and Svaiter](#page-134-5) [\(2008\)](#page-134-5) for solving Problem [3.1](#page-23-0) was extended to Problem [3.7.](#page-24-0) More precisely, it employs the geometric principle of Proposition [4.10](#page-38-0) as follows. Let us assume that, at iteration n , points $(a_n, a_n^*) \in \text{gra } A$ and $(b_n, b_n^*) \in \text{gra } B$ are available and set

$$
m_n = (a_n, b_n^*)
$$
 and $m_n^* = (a_n^* + L^* b_n^*, b_n - La_n).$ (9.4)

Then it is clear from [\(9.3\)](#page-106-0) that $(m_n, m_n^*) \in \text{gra }\mathcal{K}$. Hence, given $\lambda_n \in]0,2[$, iteration *n* of algorithm [\(4.32\)](#page-38-1) updates $(x_n, y_n^*) \in \mathbf{X}$ via the routine

$$
\begin{cases}\n(t_n, t_n^*) = (b_n - La_n, a_n^* + L^* b_n^*) \\
\tau_n = ||t_n||^2 + ||t_n^*||^2 \\
\text{if } \tau_n > 0 \\
\theta_n = \frac{\lambda_n}{\tau_n} \max\{0, \langle x_n | t_n^* \rangle + \langle t_n | y_n^* \rangle - \langle a_n | a_n^* \rangle - \langle b_n | b_n^* \rangle\} \\
\text{else } \theta_n = 0 \\
(x_{n+1}, y_{n+1}^*) = (x_n - \theta_n t_n^*, y_n^* - \theta_n t_n).\n\end{cases} \tag{9.5}
$$

In view of Proposition [4.10\(](#page-38-0)[ii\)](#page-38-2), the task is now to specify $(a_n, a_n^*) \in \text{gra } A$ and $(b_n, b_n^*) \in \text{gra } B$ so as to guarantee that $m_n - (x_n, y_n^*) \to 0$ and $m_n^* \to 0$, that is,

$$
a_n - x_n \to 0
$$
, $b_n^* - y_n^* \to 0$, $b_n - La_n \to 0$ and $a_n^* + L^* b_n^* \to 0$. (9.6)

Given γ_n and σ_n in]0, + ∞ [, choosing

$$
(a_n, a_n^*) = (J_{\gamma_n A}(x_n - \gamma_n L^* y_n^*), \gamma_n^{-1} (x_n - J_{\gamma_n A}(x_n - \gamma_n L^* y_n^*)) - L^* y_n^*) \tag{9.7}
$$

and

$$
(b_n, b_n^*) = (J_{\sigma_n}B(Lx_n + \sigma_n y_n^*), \sigma_n^{-1}(Lx_n - J_{\sigma_n}B(Lx_n + \sigma_n y_n^*)) + y_n^*)
$$
(9.8)

satisfies this requirement, which leads to the following result.

Proposition 9.1 [\(Alotaibi](#page-126-1) *et al.* **[2014\)](#page-126-1).** Let $A: \mathcal{H} \rightarrow 2^{\mathcal{H}}$ and $B: \mathcal{G} \rightarrow 2^{\mathcal{G}}$ be maximally monotone, and let $L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$. Suppose that the set Z of solutions to the primal inclusion

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + L^*(B(Lx))$ (9.9)

is not empty and let Z^* be the set of solutions to the dual inclusion

find
$$
y^* \in \mathcal{G}
$$
 such that $0 \in -L(A^{-1}(-L^*y^*)) + B^{-1}y^*$. (9.10)

Let $\varepsilon \in]0,1[$, let $(\gamma_n)_{n\in\mathbb{N}}$ and $(\sigma_n)_{n\in\mathbb{N}}$ be sequences in $[\varepsilon,1/\varepsilon]$, let $(\lambda_n)_{n\in\mathbb{N}}$ be a
sequence in $[\varepsilon, 2 - \varepsilon]$, let $x_0 \in \mathcal{H}$, and let y_0^* $\zeta_0^* \in \mathcal{G}$. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\na_n = J_{\gamma_n} A(x_n - \gamma_n L^* y_n^*) \\
l_n = Lx_n \\
b_n = J_{\sigma_n} B(l_n + \sigma_n y_n^*) \\
t_n = b_n - La_n \\
t_n^* = \gamma_n^{-1} (x_n - a_n) + \sigma_n^{-1} L^* (l_n - b_n) \\
\tau_n = ||t_n||^2 + ||t_n^*||^2 \\
\text{if } \tau_n > 0 \\
\lfloor \theta_n = \lambda_n (\gamma_n^{-1} ||x_n - a_n||^2 + \sigma_n^{-1} ||l_n - b_n||^2)/\tau_n \\
\text{else } \theta_n = 0 \\
x_{n+1} = x_n - \theta_n t_n^* \\
y_{n+1}^* = y_n^* - \theta_n t_n.\n\end{cases} (9.11)
$$

Then $(x_n)_{n \in \mathbb{N}}$ converges weakly to a point $x \in Z$ and $(y_n^*)_{n \in \mathbb{N}}$ converges weakly to a point $y^* \in Z^*$.

Remark 9.2. Here are notable instantiations of Proposition [9.1.](#page-107-0)

- (i) The first instance of [\(9.11\)](#page-108-0) in the literature seems to be that of [Dong](#page-134-0) [\(2005\)](#page-134-0), where H and G are Euclidean spaces, $A = 0$, and $(\forall n \in \mathbb{N})$ $\gamma_n = \sigma_n = 1$ and $\lambda_n = \lambda \in]0, 2[$. Convergence of the primal sequence $(x_n)_{n \in \mathbb{N}}$ was established by different means.
- (ii) In the setting of Problem [3.1](#page-23-0) (i.e. $G = H$ and $L = Id$), [\(9.11\)](#page-108-0) was studied in [Eckstein and Svaiter](#page-134-1) [\(2008\)](#page-134-1). Under the additional assumptions that $A + B$ is maximally monotone or that H is finite-dimensional, weak convergence was established in [Eckstein and Svaiter](#page-134-1) [\(2008,](#page-134-1) Proposition 3) for a version of [\(9.11\)](#page-108-0) which allows for an additional relaxation parameter in the definition of a_n .

Remark 9.3. So far, we have presented several methods to solve Problem [3.7;](#page-24-0) see Proposition [5.15,](#page-51-0) Example [5.20,](#page-55-0) Proposition [7.3](#page-69-0) and Remark [8.51.](#page-105-0) Some features that distinguish the splitting algorithm [\(9.11\)](#page-108-0) from them are as follows.

- (i) At each iteration of [\(9.11\)](#page-108-0), different proximal parameters γ_n and σ_n can be used for the operators A and B and, since ε is chosen by the user, their values can be arbitrarily large.
- (ii) The execution of [\(9.11\)](#page-108-0) does not require that $||L||$ or an approximation thereof be known, or the inversion of linear operators.
- (iii) A variant of [\(9.11\)](#page-108-0) exploiting the cocoercivity of some of the operators and activating them via Euler steps is discussed in [Johnstone and Eckstein](#page-137-0) [\(2021\)](#page-137-0).
- (iv) The complexity of certain special cases and variants of (9.11) is investigated in [Johnstone and Eckstein](#page-137-1) [\(2019\)](#page-137-1) and [Machado and Sicre](#page-138-0) [\(2023\)](#page-138-0).

The following strongly convergent projective splitting algorithm results from Proposition [4.11.](#page-38-0)

Proposition 9.4 [\(Alotaibi](#page-126-0) *et al.* **[2015\)](#page-126-0).** Let $A: \mathcal{H} \rightarrow 2^{\mathcal{H}}$ and $B: \mathcal{G} \rightarrow 2^{\mathcal{G}}$ be maximally monotone, and let $L \in \mathcal{B}(\mathcal{H}, \mathcal{G})$. Suppose that the set Z of solutions to the primal inclusion

find
$$
x \in \mathcal{H}
$$
 such that $0 \in Ax + L^*(B(Lx))$ (9.12)

is not empty and let Z^* be the set of solutions to the dual inclusion

find
$$
y^* \in \mathcal{G}
$$
 such that $0 \in -L(A^{-1}(-L^*y^*)) + B^{-1}y^*$. (9.13)

Let $\varepsilon \in]0,1[$, let $(\gamma_n)_{n \in \mathbb{N}}$ and $(\sigma_n)_{n \in \mathbb{N}}$ be sequences in $[\varepsilon, 1/\varepsilon]$, let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in [ε , 1], let $x_0 \in \mathcal{H}$, and let y_0^* $\zeta_0^* \in \mathcal{G}$. Iterate

for
$$
n = 0, 1, ...
$$

\n $a_n = J_{\gamma_n}A(x_n - \gamma_n L^* y_n^*)$
\n $l_n = Lx_n$
\n $b_n = J_{\sigma_n}B(l_n + \sigma_n y_n^*)$
\n $t_n = b_n - La_n$
\n $t_n^* = \gamma_n^{-1}(x_n - a_n) + \sigma_n^{-1}L^*(l_n - b_n)$
\n $\tau_n = ||t_n||^2 + ||t_n^*||^2$
\nif $\tau_n > 0$
\n $\left[\theta_n = \lambda_n (\gamma_n^{-1} ||x_n - a_n||^2 + \sigma_n^{-1} ||l_n - b_n||^2)/\tau_n \right]$
\nelse $\theta_n = 0$
\n $r_n = x_n - \theta_n t_n^*$
\n $r_n^* = y_n^* - \theta_n t_n$
\n $\chi_n = \theta_n (\langle x_0 - x_n | t_n^* \rangle + \langle t_n | y_0^* - y_n^* \rangle)$
\n $\mu_n = ||x_0 - x_n||^2 + ||y_0^* - y_n^*||^2$
\n $\gamma_n = \theta_n^2 \tau_n$
\n $\rho_n = \mu_n v_n - \chi_n^2$
\nif $\rho_n = 0$ and $\chi_n \ge 0$
\n $\begin{vmatrix} x_{n+1} = r_n \\ x_{n+1}^* = r_n^* \\ y_{n+1}^* = r_n^* \end{vmatrix}$
\nif $\rho_n > 0$ and $\chi_n v_n \ge \rho_n$
\n $\begin{vmatrix} x_{n+1} = x_0 - \theta_n (1 + \chi_n / v_n) t_n \\ y_{n+1}^* = y_0^* - \theta_n (1 + \chi_n / v_n) t_n \\ \vdots \\ \gamma_{n+1}^* = y_0^* - \theta_n (1 + \chi_n / v_n) t_n \\ \vdots \\ \gamma_{n+1}^* = y_n^* + (\nu_n / \rho_n) (\chi_n (x_0 - x_n) - \mu_n \theta_n t_n).$

Then $(x_n)_{n \in \mathbb{N}}$ converges strongly to a point $x \in \mathbb{Z}$ and $(y_n^*)_{n \in \mathbb{N}}$ converges strongly to a point $y^* \in Z^*$.

9.3. Block-iterative asynchronous method

We consider a refinement of Problem [3.11](#page-26-0) in which the primal variable is specified in terms of finitely many coordinates, say $x = (x_1, \ldots, x_m)$, where each x_i lies in a Hilbert space \mathcal{H}_i . Such coupled systems of inclusions arise in particular in multivariate optimization [\(Acker and Prestel](#page-126-1) [1980,](#page-126-1) [Attouch, Bolte, Redont and](#page-127-0) [Soubeyran](#page-127-0) [2008,](#page-127-0) [Attouch](#page-127-1) *et al.* [2010,](#page-127-1) [Combettes](#page-132-0) [2013](#page-132-0)*b*), domain decomposition methods [\(Alduncin](#page-126-2) [2023,](#page-126-2) [Attouch](#page-127-2) *et al.* [2016,](#page-127-2) [2011\)](#page-127-3), image processing [\(Aujol and](#page-127-4) [Chambolle](#page-127-4) [2005,](#page-127-4) [Briceño-Arias, Combettes, Pesquet and Pustelnik](#page-130-0) [2011,](#page-130-0) [Chaux](#page-131-0) *[et al.](#page-131-0)* [2013,](#page-131-0) [Vese and Osher](#page-143-0) [2004\)](#page-143-0), game theory [\(Belgioioso](#page-128-0) *et al.* [2021,](#page-128-0) [Börgens](#page-129-0) [and Kanzow](#page-129-0) [2021,](#page-129-0) [Briceño-Arias and Combettes](#page-129-1) [2013,](#page-129-1) [Bùi and Combettes](#page-130-1) [2022](#page-130-1)*a*), network flow problems [\(Bertsekas](#page-128-1) [1998,](#page-128-1) [Bùi](#page-130-2) [2022](#page-130-2)*a*, [Rockafellar](#page-141-0) [1984,](#page-141-0) [1995\)](#page-141-1), machine learning [\(Briceño-Arias, Chierchia, Chouzenoux and Pesquet](#page-130-3) [2019,](#page-130-3) [Jenatton](#page-137-2) *[et al.](#page-137-2)* [2011,](#page-137-2) [Micchelli, Morales and Pontil](#page-139-0) [2013,](#page-139-0) [Villa, Rosasco, Mosci and Verri](#page-143-1) [2014\)](#page-143-1), signal processing [\(Briceño-Arias and Combettes](#page-129-2) [2009\)](#page-129-2), mean field games [\(Briceño-Arias](#page-130-4) *et al.* [2018\)](#page-130-4), statistics [\(Combettes and Müller](#page-132-1) [2020,](#page-132-1) [Yan and Bien](#page-144-0) [2021\)](#page-144-0), tensor completion [\(Gandy, Recht and Yamada](#page-135-0) [2011,](#page-135-0) [Mizoguchi and Yamada](#page-139-1) [2019\)](#page-139-1) and semi-definite programming [\(Hu, Sotirov and Wolkowicz](#page-137-3) [2023,](#page-137-3) [Oliveira,](#page-140-0) [Wolkowicz and Xu](#page-140-0) [2018\)](#page-140-0).

Problem 9.5. Let $I = \{1, \ldots, m\}$ and $K = \{1, \ldots, p\}$ be nonempty finite sets. For every $i \in I$ and every $k \in K$, let \mathcal{H}_i and \mathcal{G}_k be real Hilbert spaces, let $A_i : \mathcal{H}_i \to$ $2^{\mathcal{H}_i}$ and $B_k: \mathcal{G}_k \to 2^{\mathcal{G}_k}$ be maximally monotone, and let $L_{ki} \in \mathcal{B}(\mathcal{H}_i, \mathcal{G}_k)$. Set

$$
\mathcal{H} = \bigoplus_{i \in I} \mathcal{H}_i \quad \text{and} \quad \mathcal{G} = \bigoplus_{k \in K} \mathcal{G}_k. \tag{9.15}
$$

The objective is to solve the primal inclusion

find
$$
\mathbf{x} \in \mathcal{H}
$$
 such that $(\forall i \in I) \ 0 \in A_i x_i + \sum_{k \in K} L_{ki}^* \left(B_k \left(\sum_{j \in I} L_{kj} x_j \right) \right)$ (9.16)

together with the dual inclusion

find
$$
\mathbf{y}^* \in \mathcal{G}
$$
 such that $(\exists \mathbf{x} \in \mathcal{H})$
$$
\begin{cases} (\forall i \in I) \ x_i \in A_i^{-1} \left(-\sum_{k \in K} L_{ki}^* y_k^* \right), \\ (\forall k \in K) \ \sum_{i \in I} L_{ki} x_i \in B_k^{-1} y_k^*. \end{cases}
$$
(9.17)

Remark 9.6. There is an oversight in the dual problem given in [Combettes and](#page-132-2) [Eckstein](#page-132-2) [\(2018,](#page-132-2) Problem 1): the correct formulation of the dual inclusion is [\(9.17\)](#page-110-0).

The counterpart of Lemma [3.12](#page-26-1) for Problem [9.5](#page-110-1) is as follows.

Lemma 9.7. In the setting of Problem [9.5,](#page-110-1) set $X = H \oplus G$, and let Z and Z^* be the sets of solutions to [\(9.16\)](#page-110-2) and [\(9.17\)](#page-110-0), respectively. Define the Kuhn–Tucker operator of Problem [9.5](#page-110-1) as

$$
\mathcal{K}: \mathbf{X} \to 2^{\mathbf{X}}: (x, y^*) \mapsto
$$
\n
$$
\left(A_1 x_1 + \sum_{k \in K} L_{k1}^* y_k^*\right) \times \cdots \times \left(A_m x_m + \sum_{k \in K} L_{km}^* y_k^*\right)
$$
\n
$$
\times \left(-\sum_{i \in I} L_{1i} x_i + B_1^{-1} y_1^*\right) \times \cdots \times \left(-\sum_{i \in I} L_{pi} x_i + B_p^{-1} y_p^*\right) \tag{9.18}
$$

and the set of Kuhn–Tucker points as zer K . Then the following hold:

- (i) κ is maximally monotone.
- (ii) zer \mathcal{K} is a closed convex subset of $Z \times Z^*$.
- (iii) $\mathbb{Z}^* \neq \emptyset \Leftrightarrow \text{zer } \mathcal{K} \neq \emptyset \Rightarrow \mathbb{Z} \neq \emptyset.$

Example 9.8. In the setting of Problem [9.5,](#page-110-1) set $X = H \oplus G$, let K be the Kuhn– Tucker operator of [\(9.18\)](#page-111-0), and let $\mathcal{T} : \mathbf{X} \to \mathcal{H} : (x, y^*) \mapsto x$. Then it follows from Lemma [9.7](#page-111-1)[\(ii\)](#page-111-2) that $(X, \mathcal{K}, \mathcal{T})$ is an embedding of [\(9.16\)](#page-110-2).

When the monotone operators $(A_i)_{1 \leq i \leq m}$ and $(B_k)_{1 \leq k \leq n}$ are taken to be subdifferentials, Problem [9.5](#page-110-1) specializes to a multivariate minimization problem under a suitable qualification condition.

Example 9.9. Define H and G as in Problem [9.5.](#page-110-1) For every $i \in I$ and every $k \in K$, let $f_i \in \Gamma_0(\mathcal{H}_i)$, let $g_k \in \Gamma_0(\mathcal{G}_k)$, and let $L_{ki} \in \mathcal{B}(\mathcal{H}_i, \mathcal{G}_k)$. Suppose that (existence of a Kuhn–Tucker point)

$$
(\exists x \in \mathcal{H})(\exists y^* \in \mathcal{G}) \begin{cases} (\forall i \in I) & -\sum_{k \in K} L^*_{ki} y^*_k \in \partial f_i(x_i), \\ (\forall k \in K) & \sum_{i \in I} L_{ki} x_i \in \partial g^*_k(y^*_k). \end{cases} \tag{9.19}
$$

The objective is to solve the primal minimization problem

$$
\underset{x \in \mathcal{H}}{\text{minimize}} \quad \sum_{i \in I} f_i(x_i) + \sum_{k \in K} g_k \left(\sum_{i \in I} L_{ki} x_i \right) \tag{9.20}
$$

together with its dual problem

$$
\underset{\mathbf{y}^* \in \mathcal{G}}{\text{minimize}} \quad \sum_{i \in I} f_i^* \left(- \sum_{k \in K} L_{ki}^* y_k^* \right) + \sum_{k \in K} g_k^* (y_k^*). \tag{9.21}
$$

In an attempt to recast Problem [9.5](#page-110-1) as a realization of Problem [3.7,](#page-24-0) let us define

$$
\begin{cases}\nA: \mathcal{H} \to 2^{\mathcal{H}}: x \mapsto A_1 x_1 \times \cdots \times A_m x_m, \\
B: \mathcal{G} \to 2^{\mathcal{G}}: y \mapsto B_1 y_1 \times \cdots \times B_p y_p, \\
L: \mathcal{H} \to \mathcal{G}: x \mapsto (\sum_{i \in I} L_{1i} x_i, \dots, \sum_{i \in I} L_{pi} x_i).\n\end{cases} \tag{9.22}
$$

Upon injecting these operators into [\(9.11\)](#page-108-0) and invoking Example [2.37,](#page-20-0) we obtain an algorithm that requires that $m + p$ resolvents be evaluated at each iteration. In largescale problems, *and* $*p*$ *can be huge and this requirement poses implementation* issues as the only information flow within an iteration is from the m operators $(A_i)_{i \in I}$ calculations to the p operators $(B_k)_{k \in K}$ calculations. This results in an algorithm in which large blocks of calculations must be performed before any information is exchanged between subsystems. Thus, if some small subset of the subsystems represented by the operators $(A_i)_{i \in I}$ or $(B_k)_{k \in K}$ are more computationintensive than others, load balancing can become problematic: most processors may have to sit idle while the remaining few complete their tasks. More generally, none of the methods discussed so far can handle block-processing or asynchronicity.

The algorithm we present now was conceived in [Combettes and Eckstein](#page-132-2) [\(2018\)](#page-132-2) around combined objectives which were beyond the reach of the existing splitting algorithms.

- \bullet *Block iterations.* At iteration n , it necessitates calculation of new points in the graphs of only some of the operators, say $(A_i)_{i \in I_n}$ and $(B_k)_{k \in K_n}$ with $I_n \subset I$ and $K_n \subset K$. The deterministic control sequences $(I_n)_{n \in \mathbb{N}}$ and $(K_n)_{n \in \mathbb{N}}$ dictate how frequently the various operators are used.
- *Asynchronicity*. A new point $(a_{i,n}, a_{i,n}^*) \in \text{gra } A_i$ being incorporated into the calculations at iteration *n* may be based on data $x_{i, \pi_i(n)}$ and $(y^*_{k, \pi_i(n)})_{k \in K}$ available at some possibly earlier iteration $\pi_i(n) \leq n$. Therefore, the calculation of $(a_{i,n}, a_{i,n}^*)$ could have been initiated at iteration $\pi_i(n)$, with its results becoming available only at iteration *n*. Likewise, for every $k \in K_n$, the computation of $(b_{k,n}, b_{k,n}^*) \in \text{gra } B_k$ can be initiated at some iteration $\omega_k(n) \leq n$, based on $(x_{i,\omega_k(n)})_{i \in I}$ and $y_{k,\omega_k(n)}^*$.
- *Convergence.* It guarantees (weak or strong) convergence of the iterates to primal and dual solutions.

Remark 9.10. Regarding block iterations for Problem [9.5,](#page-110-1) a product space version of the Douglas–Rachford algorithm was introduced in [Combettes and Pesquet](#page-133-0) [\(2015\)](#page-133-0), which features random activation of the blocks. A random block-iterative version of the forward–backward algorithm was also proposed in [Combettes and](#page-133-0) [Pesquet](#page-133-0) [\(2015\)](#page-133-0), which in [Pesquet and Repetti](#page-140-1) [\(2015\)](#page-140-1) led to algorithms for Problem [9.5](#page-110-1) via the renorming techniques presented in Section [8.4.6;](#page-98-0) for specialized

block-iterative forward–backward algorithms tailored for instances of Example [9.9,](#page-111-3) see [Briceño-Arias](#page-130-3) *et al.* [\(2019\)](#page-130-3), [Liu and Wright](#page-138-1) [\(2015\)](#page-138-1), [Salzo and Villa](#page-142-0) [\(2022\)](#page-142-0) and [Traoré, Salzo and Villa](#page-143-2) [\(2023\)](#page-143-2). These methods differ from the deterministic ones presented below in that they operate under stochastic assumptions on the underlying processes, have a less predictable computational load over the iterations, have less freedom in the choice of the proximal parameters, and offer only almost sure convergence guarantees; see also [Bùi, Combettes and Woodstock](#page-131-1) [\(2022\)](#page-131-1) for numerical comparisons.

Going back to (9.5) in the setting of (9.22) and Lemma [9.7,](#page-111-1) what is actually needed at iteration *n* to create the half-space containing zer $\mathcal K$ are points

$$
\begin{cases}\n(a_{i,n}, a_{i,n}^*) \in \text{gra } A_i, & \text{for } i \in I, \\
(b_{k,n}, b_{k,n}^*) \in \text{gra } B_k, & \text{for } k \in K.\n\end{cases}
$$
\n(9.23)

The key observation is that not all of these points have to be new in order to obtain a new half-space. In other words, we can update only some of them while keeping old ones and still create a new half-space onto which the current primal–dual iterate $(x_n, y_n^*) = (x_{1,n}, \dots, x_{m,n}, y_{1,n}^*, \dots, y_{p,n}^*)$ will be projected. How often the points in the individual graphs should be updated, and in which fashion, will be regulated by the following rules.

Assumption 9.11. Given $0 \lt R \in \mathbb{N}$, $(I_n)_{n \in \mathbb{N}}$ is a sequence of nonempty subsets of *I*, and $(K_n)_{n \in \mathbb{N}}$ is a sequence of nonempty subsets of K such that

$$
I_0 = I
$$
, $K_0 = K$ and $(\forall n \in \mathbb{N})$
$$
\begin{cases} \n\bigcup_{j=n}^{n+R-1} I_j = I, \\ \n\bigcup_{j=n}^{n+R-1} K_j = K. \n\end{cases}
$$
(9.24)

Assumption 9.12. $T \in \mathbb{N}$ and, for every $i \in I$ and every $k \in K$, $(\pi_i(n))_{n \in \mathbb{N}}$ and $(\omega_k(n))_{n\in\mathbb{N}}$ are sequences in N such that $(\forall n \in \mathbb{N})$ $n - T \leq \pi_i(n) \leq n$ and $n - T \leq \omega_k(n) \leq n$.

With these considerations and by making selections for the updated points $(a_{i,n}, a_{i,n}^*)_{i \in I_n}$ and $(b_{k,n}^*, b_{k,n}^*)_{k \in I_n}$ akin to those of [\(9.7\)](#page-107-2) and [\(9.8\)](#page-107-3), we arrive at the following realization of [\(9.5\)](#page-107-1).

Algorithm 9.13. Consider the setting of Problem [9.5,](#page-110-1) suppose that Assump-tions [9.11](#page-113-0) and [9.12](#page-113-1) are in force, let $\varepsilon \in [0,1]$, and let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, 2-\varepsilon]$. For every $i \in I$, let $(\gamma_{i,n})_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, 1/\varepsilon]$ and let $x_{i,0} \in \mathcal{H}_i$.

For every $k \in K$, let $(\sigma_{k,n})_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, 1/\varepsilon]$ and let $y_{k,0}^* \in \mathcal{G}_k$. Iterate

for
$$
n = 0, 1, ...
$$

\nfor every $i \in I_n$
\n
$$
\begin{cases}\n\int_{i,n}^{x} f_{i,n} = \sum_{k \in K} L_{ki}^{*} y_{k,\pi_i(n)}^{*} \\
a_{i,n} = J_{\gamma_{i,\pi_i(n)} \Delta_i} (x_{i,\pi_i(n)} - \gamma_{i,\pi_i(n)} l_{i,n}^{*}) \\
a_{i,n}^{*} = \gamma_{i,\pi_i(n)}^{-1} (x_{i,\pi_i(n)} - a_{i,n}) - l_{i,n}^{*} \\
\text{for every } i \in I \setminus I_n \\
\int (a_{i,n}, a_{i,n}^{*}) = (a_{i,n-1}, a_{i,n-1}^{*}) \\
\text{for every } k \in K_n\n\end{cases}
$$
\n
$$
\begin{cases}\nI_{k,n} = \sum_{i \in I} L_{ki} x_{i,\omega_k(n)} \\
b_{k,n} = J_{\sigma_{k,\omega_k(n)} B_k} (l_{k,n} + \sigma_{k,\omega_k(n)} x_{k,\omega_k(n)}) \\
b_{k,n}^{*} = J_{\sigma_{k,\omega_k(n)}} + \sigma_{k,\omega_k(n)}^{-1} (l_{k,n} - b_{k,n}) \\
\text{for every } k \in K \setminus K_n \\
\int (b_{k,n}, b_{k,n}^{*}) = (b_{k,n-1}, b_{k,n-1}^{*}) \\
\text{for every } i \in I\n\end{cases}
$$
\n
$$
\begin{cases}\nI_{i,n}^{*} = a_{i,n}^{*} + \sum_{k \in K} L_{ki}^{*} b_{k,n}^{*} \\
I_{k,n}^{*} = b_{k,n} - \sum_{i \in I} L_{ki} a_{i,n} \\
\tau_n = \sum_{i \in I} |l_{i,n}^{*}|^{2} + \sum_{k \in K} |l_{k,n}^{*}|^{2} \\
\text{if } \tau_n > 0 \\
\theta_n = \frac{\lambda_n}{\tau_n} \max\{0, \sum_{i \in I} (\langle x_{i,n} | t_{i,n}^{*} \rangle - \langle a_{i,n} | a_{i,n}^{*} \rangle) \} \\
\text{else } \theta_n = 0 \\
\text{for every } i \in I\n\end{cases}
$$
\n
$$
\begin{cases}\nI_{i,n+1} = x_{i,n} - \theta_n t_{i,n}^{*} \\
\text{for every } k \in K\n\end{cases}
$$

Weak convergence is obtained by applying the principles of Proposition [4.10\(](#page-38-1)[ii\)](#page-38-2).

Theorem 9.14 [\(Combettes and Eckstein](#page-132-2) [2018\)](#page-132-2). Consider the setting of Prob-lem [9.5](#page-110-1) and Algorithm [9.13,](#page-113-2) and suppose that the Kuhn–Tucker operator κ of [\(9.18\)](#page-111-0) has zeros. Then, for every $i \in I$, $(x_{i,n})_{n \in \mathbb{N}}$ converges weakly to a point $x_i \in \mathcal{H}_i$ and, for every $k \in K$, $(y_{k,n}^*)_{n \in \mathbb{N}}$ converges weakly to a point $y_k^* \in \mathcal{G}_k$. In addition, $(x_i)_{i \in I}$ solves the primal problem [\(9.16\)](#page-110-2) and $(y_k^*)_{k \in K}$ solves the dual problem [\(9.17\)](#page-110-0).

Remark 9.15. Here are a few comments on algorithm [\(9.13\)](#page-113-2).

(i) The synchronous implementation is obtained by taking, for every $n \in \mathbb{N}$, every $i \in I_n$ and every $k \in K_n$, $\pi_i(n) = \omega_k(n) = n$.

- (ii) We recover Theorem 4.3 of [Alotaibi](#page-126-3) *et al.* [\(2014\)](#page-126-3) (and in particular Propos-ition [9.4](#page-109-0) when $m = p = 1$) in the special case when the implementation is synchronous, and at every iteration *n*, every operator is used (i.e. $I_n = I$ and $K_n = K$), with $\gamma_{i,n} = \gamma_n$ for every $i \in I$ and $\sigma_{k,n} = \sigma_n$ for every $k \in K$.
- (iii) The specialization of Theorem [9.14](#page-114-0) to the minimization setting of Ex-ample [9.9](#page-111-3) is obtained by replacing each $J_{\gamma_{i,\pi_i(n)}A_i}$ with prox $_{\gamma_{i,\pi_i(n)}f_i}$ and each $J_{\sigma_{k,\omega_k(n)}B_k}$ with prox $_{\sigma_{k,\omega_k(n)}B_k}$. Numerical experiments are presented in [Bùi](#page-131-1) *[et al.](#page-131-1)* [\(2022\)](#page-131-1) in the context of signal recovery and machine learning, and in [Eckstein, Watson and Woodruff](#page-135-1) [\(2023\)](#page-135-1) in the context of stochastic programming.
- (iv) For the strongly convergent variant of Theorem [9.14](#page-114-0) based on Proposition [4.11,](#page-38-0) see [Combettes and Eckstein](#page-132-2) [\(2018,](#page-132-2) Theorem 15).
- (v) When $m = 1$ and $A = 0$, a variant that takes into account the fact that some of the operators $(B_k)_{k \in K}$ may be monotone and Lipschitzian, and which activate them via Euler steps is presented in [Johnstone and Eckstein](#page-137-4) [\(2022\)](#page-137-4); see also [Johnstone and Eckstein](#page-137-5) [\(2020\)](#page-137-5).

10. Block-iterative saddle projective splitting

10.1. Preview

In all the algorithms discussed so far, each monotone operator has one of three properties: it is set-valued, single-valued and cocoercive, or single-valued and Lipschitzian. In addition, at each iteration, a set-valued operator is used once via its resolvents, a cocoercive operator once via a Euler step and a Lipschitzian operator twice via Euler steps. This is particularly the case in the forward–backward–halfforward algorithm of Section [8.5,](#page-102-0) the objective of which is to find a zero of

$$
M = A + C + Q, \text{ where } \begin{cases} A: \mathcal{H} \to 2^{\mathcal{H}} & \text{is maximally monotone,} \\ C: \mathcal{H} \to \mathcal{H} & \text{is cocoercive,} \\ Q: \mathcal{H} \to \mathcal{H} & \text{is monotone and Lipschitzian.} \end{cases}
$$
 (10.1)

J. On the other hand, the Kuhn–Tucker projective splitting techniques of Section [9](#page-106-0) activate all the operators via their resolvents (exceptions were noted in Remarks [9.3](#page-108-1)[\(iii\)](#page-108-2) and $9.15(v)$ $9.15(v)$, but they concern special cases of Problem [9.5\)](#page-110-1). Furthermore, they are not designed to handle problems such as [\(7.37\)](#page-74-0) or [\(8.109\)](#page-99-0), which incorporate parallel sums.

In this section, following [Bùi and Combettes](#page-131-2) [\(2022](#page-131-2)*b*), we unify all the problem formulations encountered in Sections [5](#page-42-0)[–9](#page-106-0) by including parallel sums in the system of monotone inclusions of Problem [9.5,](#page-110-1) and decomposing each operator in the resulting problem as in [\(10.1\)](#page-115-1). In addition, nonlinear coupling operators $(R_i)_{i \in I}$ are incorporated.

Problem 10.1. Let $(\mathcal{H}_i)_{i \in I}$ and $(\mathcal{G}_k)_{k \in K}$ be finite families of real Hilbert spaces, and set

$$
\mathcal{H} = \bigoplus_{i \in I} \mathcal{H}_i \quad \text{and} \quad \mathcal{G} = \bigoplus_{k \in K} \mathcal{G}_k. \tag{10.2}
$$

For every $i \in I$ and every $k \in K$, suppose that the following are satisfied:

- [a] $A_i: \mathcal{H}_i \to 2^{\mathcal{H}_i}$ is maximally monotone, $C_i: \mathcal{H}_i \to \mathcal{H}_i$ is cocoercive with constant $\alpha_i^c \in [0, +\infty[, Q_i: \mathcal{H}_i \to \mathcal{H}_i$ is monotone and Lipschitzian with constant $\alpha_i^{\ell} \in [0, +\infty[$, and $R_i: \mathcal{H} \to \mathcal{H}_i$.
- [b] $B_k^m: \mathcal{G}_k \to 2^{\mathcal{G}_k}$ is maximally monotone, $B_k^c: \mathcal{G}_k \to \mathcal{G}_k$ is cocoercive with constant $\beta_k^c \in]0, +\infty[$, and $B_k^f : \mathcal{G}_k \to \mathcal{G}_k$ is monotone and Lipschitzian with constant $\beta_k^{\ell} \in [0, +\infty[$.
- [c] $D_k^m: \mathcal{G}_k \to 2^{\mathcal{G}_k}$ is maximally monotone, $D_k^c: \mathcal{G}_k \to \mathcal{G}_k$ is cocoercive with constant $\delta_k^c \in]0, +\infty[$, and $D_k^f : \mathcal{G}_k \to \mathcal{G}_k$ is monotone and Lipschitzian with constant $\delta_k^{\ell} \in [0, +\infty[$.

$$
[d] L_{ki} \in \mathcal{B}(\mathcal{H}_i, \mathcal{G}_k).
$$

In addition,

[e] $\mathbf{R}: \mathcal{H} \to \mathcal{H}: \mathbf{x} \mapsto (R_i \mathbf{x})_{i \in I}$ is monotone and Lipschitzian with constant $y \in [0, +\infty)$.

The objective is to solve the primal problem

find
$$
\mathbf{x} = (x_i)_{i \in I} \in \mathcal{H}
$$
 such that $(\forall i \in I) \ 0 \in A_i x_i + C_i x_i + Q_i x_i + R_i \mathbf{x}$
+
$$
\sum_{k \in K} L_{ki}^* \left(\left(\left(B_k^m + B_k^c + B_k^{\ell} \right) \square \left(D_k^m + D_k^c + D_k^{\ell} \right) \right) \left(\sum_{j \in I} L_{kj} x_j \right) \right) \tag{10.3}
$$

and the associated dual problem

find
$$
\mathbf{y}^* = (y_k^*)_{k \in K} \in \mathcal{G}
$$
 such that $(\exists \mathbf{x} \in \mathcal{H})$
\n
$$
\begin{cases}\n(\forall i \in I) - \sum_{k \in K} L_{ki}^* y_k^* \in A_i x_i + C_i x_i + Q_i x_i + R_i \mathbf{x}, \\
(\forall k \in K) y_k^* \in ((B_k^m + B_k^c + B_k^{\ell}) \square (D_k^m + D_k^c + D_k^{\ell})) \left(\sum_{i \in I} L_{ki} x_i\right).\n\end{cases}
$$
\n(10.4)

Here is an instance of Problem [10.1](#page-115-2) which is not captured by previous monotone inclusion models.

Example 10.2. We consider a game-theoretic minimax problem. Let *I* be a finite set and suppose that $\emptyset \neq J \subset I$. For every $i \in I$, the strategy x_i of player i belongs to a real Hilbert space \mathcal{H}_i . A strategy profile is a point

$$
\mathbf{x} = (x_i)_{i \in I} \in \bigoplus_{i \in I} \mathcal{H}_i,\tag{10.5}
$$

and the associated profile of the players other than $i \in I$ is $\mathbf{x}_{\setminus i} = (x_j)_{j \in I \setminus \{i\}}$. For every $i \in I$ and every

$$
(x_i, \mathbf{y}) \in \mathcal{H}_i \oplus \bigoplus_{j \in I} \mathcal{H}_j,\tag{10.6}
$$

we set $(x_i; y_{i}) = (y_1, \ldots, y_{i-1}, x_i, y_{i+1}, \ldots, y_p)$. Now set

$$
\mathcal{U} = \bigoplus_{i \in I \setminus J} \mathcal{H}_i, \quad \mathcal{V} = \bigoplus_{j \in J} \mathcal{H}_j \quad \text{and} \quad \mathcal{H} = \mathcal{U} \oplus \mathcal{V}, \tag{10.7}
$$

and, for every $i \in I$, let $f_i \in \Gamma_0(\mathcal{H}_i)$. Further, let $F: \mathcal{H} \to \mathbb{R}$ be differentiable with a Lipschitzian gradient and such that, for every $u \in U$ and every $v \in V$, the functions $-F(u, \cdot)$ and $F(\cdot, v)$ are convex. We consider the multivariate minimax problem

$$
\underset{\mathbf{u}\in\mathcal{U}}{\text{minimize}} \quad \underset{\mathbf{v}\in\mathcal{V}}{\text{maximize}} \quad \sum_{i\in I\smallsetminus J} f_i(u_i) + \mathbf{F}(\mathbf{u}, \mathbf{v}) - \sum_{j\in J} f_j(v_j). \tag{10.8}
$$

Now define

$$
(\forall i \in I) \quad \mathbf{h}_i \colon \mathcal{H} \to \mathbb{R} \colon (\mathbf{u}, \mathbf{v}) \mapsto \begin{cases} F(\mathbf{u}, \mathbf{v}), & \text{if } i \in I \setminus J, \\ -F(\mathbf{u}, \mathbf{v}), & \text{if } i \in J. \end{cases} \tag{10.9}
$$

Then [\(10.8\)](#page-117-0) can be put in the form

find
$$
\mathbf{x} \in \mathcal{H}
$$
 such that $(\forall i \in I) x_i \in \text{Argmin } f_i + \mathbf{h}_i(\cdot; \mathbf{x}_{\setminus i}).$ (10.10)

Since

$$
(\forall i \in I)(\forall x \in \mathcal{H}) \quad \nabla_i h_i(x) = \begin{cases} \nabla_i F(x), & \text{if } i \in I \setminus J, \\ \nabla_i F(x), & \text{if } i \in J, \n\end{cases} \tag{10.11}
$$

the operator

$$
\mathbf{R}: \mathcal{H} \to \mathcal{H}: x \mapsto (\nabla_i h_i(x))_{i \in I} = ((\nabla_i F(x))_{i \in I \setminus J}, (-\nabla_j F(x))_{j \in J}) \tag{10.12}
$$

is monotone [\(Rockafellar](#page-141-2) [1970](#page-141-2)*b*, [1971\)](#page-141-3) and Lipschitzian. Now, for every $i \in I$, set $A_i = \partial f_i$. Then, by Fermat's rule, [\(10.10\)](#page-117-1) is equivalent to

find
$$
\mathbf{x} \in \mathcal{H}
$$
 such that $(\forall i \in I) \ 0 \in A_i x_i + R_i \mathbf{x}$, (10.13)

which shows that (10.8) is an instantiation of (10.3) . Special cases of (10.8) under the above assumptions arise in [Attouch](#page-127-1) *et al.* [\(2010\)](#page-127-1), [Combettes and Pesquet](#page-133-1) [\(2021\)](#page-133-1), [He and Monteiro](#page-136-0) [\(2015\)](#page-136-0), Nemirovski (2004), Rockafellar (1995), [Thekumparampil,](#page-143-3) [Jain, Netrapalli and Oh](#page-143-3) [\(2019\)](#page-143-3) and [Yoon and Ryu](#page-144-1) [\(2021\)](#page-144-1).

Our objective is to solve Problem [10.1](#page-115-2) with the same level of flexibility and the same primal–dual convergence guarantees as in Theorem [9.14,](#page-114-0) that is, to achieve full splitting of all the operators using an asynchronous block-iterative algorithm without knowledge of the norms of the linear operators or inversion of linear operators. In addition, all the single-valued operators should be activated via Euler steps.

10.2. Saddle operator formulation

The approach adopted in Section [9](#page-106-0) to break Problem [9.5](#page-110-1) into manageable pieces hinged on the Kuhn–Tucker operator of Lemma [9.7](#page-111-1) to obtain the embedding of Framework [1.2.](#page-4-0) This strategy does not appear to lead to a full splitting of Problem [10.1,](#page-115-2) as it contains a larger number of operators. We therefore require an embedding in a space **X** which is bigger than the primal–dual space $\mathcal{H}_1 \oplus \cdots \mathcal{H}_m \oplus \mathcal{G}_1 \oplus \cdots \oplus \mathcal{G}_p$ of Theorem [9.14.](#page-114-0) As discussed in Remark [8.51,](#page-105-0) saddle operators are defined on a bigger space than Kuhn–Tucker operators (e.g. $H \oplus G \oplus G$ versus $H \oplus G$ in [\(8.138\)](#page-105-1)) and their zeros still provide primal-dual solutions. Following Framework [1.2,](#page-4-0) as we did in Example [3.23,](#page-30-0) the methodology of *saddle projective splitting* is to introduce a saddle operator for Problem [10.1.](#page-115-2) We shall then devise asynchronous block-iterative splitting algorithms based on the geometric principles of Theorems [4.8](#page-35-0) and [4.9](#page-37-0) to find a zero of it, from which solutions to Problem [10.1](#page-115-2) will be extracted. This is outlined in the following lemma.

Lemma 10.3 [\(Bùi and Combettes](#page-131-2) [2022](#page-131-2)*b***).** Define H and G as in [\(10.2\)](#page-116-1), set $X = H \oplus G \oplus G \oplus G$ and define the saddle operator of Problem [10.1](#page-115-2) as

$$
S: \mathbf{X} \to 2^{\mathbf{X}}: (x, y, z, v^*) \mapsto
$$

\n
$$
\left(\bigtimes_{i \in I} \left(A_i x_i + C_i x_i + Q_i x_i + R_i x + \sum_{k \in K} L_{ki}^* v_k^* \right), \right. \\ \n\left. \bigtimes_{k \in K} \left(B_k^m y_k + B_k^c y_k + B_k^{\ell} y_k - v_k^* \right), \right. \\ \n\left. \bigtimes_{k \in K} \left(D_k^m z_k + D_k^c z_k + D_k^{\ell} z_k - v_k^* \right), \right. \\ \n\left. \bigtimes_{k \in K} \left\{ y_k + z_k - \sum_{i \in I} L_{ki} x_i \right\} \right), \tag{10.14}
$$

let **Z** be the set of solutions to [\(10.3\)](#page-116-0) and let \mathbb{Z}^* be the set of solutions to [\(10.4\)](#page-116-2). Then the following hold:

- (i) \mathcal{S} is maximally monotone.
- (ii) zer S is closed and convex.
- (iii) Suppose that $(x, y, z, v^*) \in \text{zer } S$. Then $(x, v^*) \in Z \times Z^*$.
- (iv) $\mathbf{Z}^* \neq \emptyset \Leftrightarrow \text{zer}\,\mathcal{S} \neq \emptyset \Rightarrow \mathbf{Z} \neq \emptyset.$

We thus obtain the following generalization of Example [3.23.](#page-30-0)

Example 10.4. In the setting of Problem [10.1,](#page-115-2) set

$$
\mathbf{X} = \mathcal{H} \oplus \mathcal{G} \oplus \mathcal{G} \oplus \mathcal{G}, \tag{10.15}
$$

let S be the saddle operator of [\(10.14\)](#page-118-0), and let

$$
\mathcal{T}: \mathbf{X} \to \mathcal{H}: (x, y, z, v^*) \mapsto x. \tag{10.16}
$$

Then it follows from Lemma [10.3](#page-118-1)[\(iii\)](#page-119-0) that (X, S, T) is an embedding of [\(10.3\)](#page-116-0).

Thus, to solve Problem [10.1](#page-115-2) via Theorem [4.8,](#page-35-0) we need a decomposition of the saddle operator [\(10.14\)](#page-118-0) as $S = W + C$, where $W: X \rightarrow 2^X$ is maximally monotone and $C: X \rightarrow X$ is α -cocoercive. This will be achieved with

$$
\mathbf{C}: \mathbf{X} \to \mathbf{X}: (x, y, z, v^*) \mapsto \left((C_i x_i)_{i \in I}, (B_k^c y_k)_{k \in K}, (D_k^c z_k)_{k \in K}, \mathbf{0} \right) \tag{10.17}
$$

and $\alpha = \min\{\alpha_i^c, \beta_k^c, \delta_k^c\}_{i \in I, k \in K}$. These considerations lead to the following implementation of [\(4.23\)](#page-36-0).

Algorithm 10.5. In the setting of Problem [10.1,](#page-115-2) set

$$
\alpha = \min \{ \alpha_i^c, \beta_k^c, \delta_k^c \}_{\substack{i \in I \\ k \in K}},
$$
\n(10.18)

let $\sigma \in [1/(4\alpha), +\infty[$ and $\varepsilon \in [0, 1]$ be such that

$$
\frac{1}{\varepsilon} > \sigma + \max \{ \alpha_i^{\ell} + \chi, \beta_k^{\ell}, \delta_k^{\ell} \}_{\substack{i \in I \\ k \in K}},
$$
\n(10.19)

and let $(\lambda_n)_{n\in\mathbb{N}}$ be a sequence in $[\varepsilon, 2-\varepsilon]$. For every $i \in I$, let $(\gamma_{i,n})_{n\in\mathbb{N}}$ be a sequence in $[\varepsilon, 1/(\alpha_i^{\ell} + \chi + \sigma)]$ and let $x_{i,0} \in \mathcal{H}_i$. For every $k \in K$, let $(\mu_{k,n})_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, 1/(\beta_k^{\ell} + \sigma)]$, let $(\rho_{k,n})_{n \in \mathbb{N}}$ be a sequence in $[\varepsilon, 1/(\delta_k^{\ell} + \sigma)]$, let $(\sigma_{k,n})_{n\in\mathbb{N}}$ be a sequence in $[\varepsilon,1/\varepsilon]$, and let $\{y_{k,0}, z_{k,0}, v_{k,0}^*\} \subset \mathcal{G}_k$. Suppose

that Assumptions [9.11](#page-113-0) and [9.12](#page-113-1) are in force and iterate

for n = 0, 1,...\nfor every *i* ∈ *I_n*\nfor every *i* ∈ *I_n*\n
$$
\begin{cases}\n\int_{t,n}^{t} = Q_i x_{i,\pi(n)} + R_i x_{\pi(i)} + \sum_{k \in K} L_{k,i}^* v_{k,\pi(i)}^*; \\
a_{i,n} = J_{\gamma_{i,\pi(i)}}^* A_i (x_{i,\pi(i)} - T_{i,\pi(i)}) (t_{i,n}^* + G_i x_{i,\pi(i)})); \\
a_{i,n}^* = \gamma_{i,\pi(i)}^{-1} (x_{i,\pi(i)}) - t_{i,n}^* + Q_i a_{i,n}; \\

b_{k,n} = J_{\mu_{k,\omega_k(n)}} D_k^{\text{max}} (z_{k,\omega_k(n)} + \mu_{k,\omega_k(n)} (u_{k,n}^* - B_k^{\text{max}} x_{k,\omega_k(n)})); \\
d_{k,n} = J_{\mu_{k,\omega_k(n)}} D_k^{\text{max}} (z_{k,\omega_k(n)} + \mu_{k,\omega_k(n)} (u_{k,n}^* - B_k^{\text{max}} x_{k,\omega_k(n)})); \\
e_{k,n}^* = J_{\mu_{k,\omega_k(n)}}^{\text{max}} (z_{k,\omega_k(n)} + \mu_{k,\omega_k(n)} (u_{k,n}^* - B_k^{\text{max}} x_{k,\omega_k(n)})); \\
e_{k,n}^* = J_{\mu_{k,\omega_k(n)}}^{\text{max}} (z_{k,\omega_k(n)} - b_{k,n}) + u_{k,n}^* + B_k^{\text{max}} b_{k,n} - e_{k,n}^*; \\
h_{k,n} = D_k^* \omega_k(n) (z_{k,\omega_k(n)} - d_{k,n}) + v_{k,n}^* + B_k^{\text{max}} b_{k,n} - e_{k,n}^*; \\
h_{k,n}
$$

10.3. Convergence

The convergence properties of Algorithm [10.5](#page-119-1) are laid out in the following theorem.

Theorem 10.6 [\(Bùi and Combettes](#page-131-2) [2022](#page-131-2)*b***).** Consider the setting of Problem[10.1](#page-115-2) and Algorithm [10.5,](#page-119-1) and suppose that the saddle operator S of [\(10.14\)](#page-118-0) has zeros. Then, for every $i \in I$, $(x_{i,n})_{n \in \mathbb{N}}$ converges weakly to a point $x_i \in \mathcal{H}_i$ and, for every $k \in K$, $(v_{k,n}^*)_{n \in \mathbb{N}}$ converges weakly to a point $v_k^* \in \mathcal{G}_k$. In addition, $(x_i)_{i \in I}$ solves the primal problem [\(10.3\)](#page-116-0) and $(v_k^*)_{k \in K}$ solves the dual problem [\(10.4\)](#page-116-2).

Remark 10.7. The strongly convergent variant of Theorem [10.6](#page-121-0) based on Theorem [4.9](#page-37-0) is proposed in [Bùi and Combettes](#page-131-2) [\(2022](#page-131-2)*b*, Theorem 2(iv)).

Remark 10.8. A fact that has not be appreciated previously is that Theorem [10.6](#page-121-0) contains as special cases various weak convergence results of Sections [7](#page-66-0)[–8.](#page-77-0) Thus, suppose that

$$
I = K = \{1\}
$$
, $R_1 = 0$ and $L_{11} = 0$. (10.21)

Then Problem [10.1](#page-115-2) reduces to finding a zero of $A_1+C_1+O_1$ (see [\(8.120\)](#page-103-0)), [\(10.20\)](#page-120-0) reduces to the forward–backward–half-forward algorithm [\(8.121\)](#page-103-1), and Theorem [10.6](#page-121-0) reduces to Proposition [8.48.](#page-102-1) This covers both the forward–backward–forward algorithm [\(7.2\)](#page-67-0) for $C_1 = 0$ (Theorem [7.1\)](#page-67-1) and the unrelaxed forward–backward algorithm [\(8.5\)](#page-78-0) for $Q_1 = 0$ (Theorem [8.1\)](#page-78-1). In a similar fashion, we can recover the multivariate forward–backward–forward algorithm of [Combettes](#page-132-0) [\(2013](#page-132-0)*b*) by choosing

$$
(\forall i \in I)(\forall k \in K)
$$
 $C_i = R_i = 0$ and $B_k^c = B_k^{\ell} = D_k^c = D_k^{\ell} = 0.$ (10.22)

Going back to the simple inclusion problem (8.120) , Theorem [10.6](#page-121-0) offers several other possibilities, for instance by implementing it with

$$
I = K = \{1\}, A_1 = A, R_1 = C_1 = Q_1 = 0, L_{11} = \text{Id},
$$

\n
$$
B_1^m = 0, B_1^c = C, B_1^{\ell} = Q, \text{ and } D_1^m = D_1^c = D_1^{\ell} = \{0\}^{-1}.
$$
 (10.23)

As mentioned earlier, Problem [10.1](#page-115-2) encompasses all the problems discussed earlier. Theorem [10.6](#page-121-0) can therefore be used to provide alternative algorithms to solve them in an asynchronous and block-iterative manner, and with operatordependent proximal parameters (these features are absent from the algorithms of Sections [5–](#page-42-0)[8\)](#page-77-0). Here is an example.

Example 10.9. In Problem [10.1,](#page-115-2) suppose that

$$
I = \{1\}, K = \{1, ..., p\}, A_1 = A, C_1 = R_1 = 0, Q_1 = Q \text{ and } (\forall k \in K)
$$

$$
L_{k1} = L_k, B_k^m = B_k, B_k^c = B_k^{\ell} = 0, D_k^m = D_k \text{ and } D_k^c = D_k^{\ell} = 0. \quad (10.24)
$$

Then we obtain the primal–dual inclusions [\(7.37\)](#page-74-0)–[\(7.38\)](#page-74-1) of Proposition [7.10,](#page-74-2) and Theorem [10.6](#page-121-0) furnishes a flexible alternative to Proposition [7.10](#page-74-2) which, in addition, places no restriction on the operators $(D_k)_{k \in K}$, with the algorithm

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{aligned}\n&\int_{n}^{h} = Qx_{\pi(n)} + \sum_{k \in K} L_{k}^{*} v_{k, \pi(n)}^{*};\\
&a_{n} = J_{\gamma_{\pi(n)}} A(x_{\pi(n)} - \gamma_{\pi(n)})_{n}^{*};\\
&a_{n}^{*} = \gamma_{\pi(n)}^{-1}(x_{\pi(n)} - a_{n}) - l_{n}^{*} + Qa_{n};\\
&\text{for every } k \in K_{n} \\
&\text{for every } k \in K_{n} \\
&\text{for } k = 1, k, \omega_{k}(n)B_{k} (x_{k}, \omega_{k}(n)) + \mu_{k}, \omega_{k}(n) v_{k, \omega_{k}(n)}^{*};\\
&\sigma_{k,n}^{*} = \sigma_{k, \omega_{k}(n)} (L_{k}x_{\omega_{k}(n)} - y_{k, \omega_{k}(n))} - z_{k, \omega_{k}(n)}) + v_{k, \omega_{k}(n)}^{*};\\
&\sigma_{k,n}^{*} = \mu_{k, \omega_{k}(n)}^{-1}(x_{k}, \omega_{k}(n)) - b_{k,n} + v_{k, \omega_{k}(n)}^{*} - e_{k,n}^{*};\\
&\sigma_{k,n}^{*} = \mu_{k, \omega_{k}(n)}^{-1}(z_{k}, \omega_{k}(n)) - d_{k,n} + v_{k, \omega_{k}(n)}^{*} - e_{k,n}^{*};\\
&\sigma_{k,n}^{*} = \mu_{k,n}^{*} - y_{k, \omega_{k}(n)}|2^{*} + ||d_{k,n} - z_{k, \omega_{k}(n)}||^{2};\\
&\sigma_{k,n} = ||b_{k,n} - y_{k, \omega_{k}(n)}||^{2} + ||d_{k,n} - z_{k, \omega_{k}(n)}||^{2};\\
&\sigma_{k,n} = b_{k,n} + d_{k,n} - L_{k}a_{n};\\
&\text{for every } k \in K \setminus K_{n} \\
&\sigma_{k,n} = b_{k,n} + d_{k,n} - L_{k}a_{n};\\
&\sigma_{k} = \sigma_{k,n-1}^{*}; d_{k,n} = d_{k,n-1}^{*}; e_{k,n}^{*} = e_{k,n-1}^{*};\\
&\sigma_{k,n}^{*} = a_{n}^{*} + \sum_{k \in K} (x_{k,n}) \\
&\sigma_{k,n}^{*
$$

Remark 10.10. In the same vein as Example [10.9,](#page-121-1) we can solve the primal–dual inclusions [\(8.109\)](#page-99-0)–[\(8.110\)](#page-100-0) of Proposition [8.44](#page-99-1) via Theorem [10.6](#page-121-0) by making the modifications $C_1 = C$ and $Q_1 = 0$ in [\(10.24\)](#page-121-2).

Ī

11. Extensions and variants

The flowchart in Figure [11.1](#page-123-0) summarizes the articulation of the main splitting methods presented in the previous sections (a similar flowchart can be drawn for the chain of strong convergence results starting with the Haugazeau principle of Theorem [4.7,](#page-33-0) then Theorem [4.9,](#page-37-0) etc.). This flowchart suggests that any extension or variant of the main theorems of Section [4](#page-30-1) (Theorems [4.2,](#page-30-2) [4.8](#page-35-0) and [4.12\)](#page-39-0) will lead to further splitting methods or, at least, different implementations of them. We discuss some of the possible variations on the basic geometric principles we have employed.

The basic operating principle of Theorem [4.2](#page-30-2) is Fejér-monotonicity, i.e. its property [\(i\)](#page-30-3). There are extensions of this notion which preserve the main weak convergence conclusions. For instance, the notion of quasi-Fejér monotonicity, introduced in [Ermol'ev and Tuniev](#page-135-2) [\(1968\)](#page-135-2) and studied in detail in [Combettes](#page-132-3) [\(2001](#page-132-3)*b*), requires that there exist a summable sequence $(\varepsilon_n)_{n\in\mathbb{N}}$ in [0, +∞[such that

$$
(\forall z \in Z)(\forall n \in \mathbb{N}) \quad ||x_{n+1} - z||^2 \le ||x_n - z||^2 + \varepsilon_n. \tag{11.1}
$$

It follows from [Combettes](#page-132-3) [\(2001](#page-132-3)*b*, Section 3) that Theorem [4.2](#page-30-2) remains valid if, for some sequence $(e_n)_{n \in \mathbb{N}}$ in H such that $\sum_{n \in \mathbb{N}} \lambda_n ||e_n|| < +\infty$, we use an approximate projection $p_n = \text{proj}_{H_n} x_n + e_n$ in [\(4.1\)](#page-30-4); see also [Combettes and Pesquet](#page-133-0) [\(2015\)](#page-133-0) for a stochastic version of this result that allows for random iteration modelling. This summable error framework can be propagated in Figure [11.1](#page-123-0) to recover approximate implementation results from [Boţ and Hendrich](#page-129-3) [\(2013\)](#page-129-3), [Combettes](#page-132-4) [\(2004,](#page-132-4) [2013](#page-132-0)*b*), [Combettes and Pesquet](#page-133-2) [\(2012\)](#page-133-2), [Condat](#page-133-3) [\(2013\)](#page-144-2), [Rockafellar](#page-141-4) [\(1976](#page-141-4)*b*) and Vũ (2013).

Figure 11.1. Articulation of the splitting methods.

Variable metric quasi-Fejér-monotonicity is an extension of [\(11.1\)](#page-123-1) described by

$$
(\forall z \in Z)(\forall n \in \mathbb{N}) \quad ||x_{n+1} - z||_{U_{n+1}}^2 \le ||x_n - z||_{U_n}^2 + \varepsilon_n, \tag{11.2}
$$

where $(U_n)_{n \in \mathbb{N}}$ is a sequence of strongly monotone operators in $\mathcal{B}(\mathcal{H})$ satisfying certain properties (Combettes and Vũ [2013\)](#page-133-4). It follows from Combettes and Vũ [\(2013,](#page-133-4) Theorem 3.3) that the conclusions of Theorem [4.2](#page-30-2) remain valid in this setting, which amounts to changing the metric of H at each iteration. See [Chen](#page-132-5) [and Rockafellar](#page-132-5) [\(1997\)](#page-132-5) and Combettes and V \tilde{u} [\(2014\)](#page-133-5) for applications to forward– backward splitting, [Rockafellar](#page-142-1) [\(2024\)](#page-142-1) for applications to multiplier methods and [Raguet and Landrieu](#page-141-5) [\(2015\)](#page-141-5) for considerations on the choice of the variable metrics. All the results derived from Theorem [4.2](#page-30-2) can be revisited in this variable-metric context. Another extension of (11.1) of interest is the multi-step quasi-Fejérmonotonicity notion

$$
(\forall z \in Z)(\forall n \in \mathbb{N}) \quad ||x_{n+1} - x||^2 \le \sum_{j=0}^{n} \mu_{n,j} ||x_j - x||^2 + \varepsilon_n \tag{11.3}
$$

of [Combettes and Glaudin](#page-132-6) [\(2021,](#page-132-6) Lemma 2.2), where $(\mu_{n,j})_{n \in \mathbb{N}, 0 \leq j \leq n}$ is an array in [0, +∞[satisfying certain properties. This setting led to deterministic block-iterative implementations of the forward–backward algorithm [\(Combettes](#page-132-6) [and Glaudin](#page-132-6) [2021,](#page-132-6) Proposition 4.9) in the spirit of methods found in [Mishchenko,](#page-139-2) [Iutzeler and Malick](#page-139-2) [\(2020\)](#page-139-2) and [Mokhtari, Gürbüzbalaban and Ribeiro](#page-139-3) [\(2018\)](#page-139-3) in the minimization case.

The hybrid proximal-extragradient/projection methods of [Solodov](#page-142-2) [\(2004\)](#page-142-2) and [Solodov and Svaiter](#page-142-3) [\(1999](#page-142-3)*a*,*[b](#page-142-4)*, [2001\)](#page-142-5) revolve around a variant of Proposition [4.10](#page-38-1) in which, at iteration $n, (m_n, m_n^*)$ is merely required to be in the graph of a perturbed version of M , which permits us to recover certain iterative methods beyond the proximal point algorithm. See also [Svaiter](#page-143-4) [\(2014\)](#page-143-4) for more recent work along these lines, where approximate resolvents are used to recover an instance of the forward–backward algorithm.

As is apparent from Figure [11.1,](#page-123-0) many convergence results we have discussed follow from Theorem [4.12.](#page-39-0) We now present a perturbed extension of it in which, at iteration *n*, the warped resolvent is applied at a point \widetilde{x}_n and not necessarily at the current iterate x_n . The special case when $C = 0$, $(q_n)_{n \in \mathbb{N}} = (w_n)_{n \in \mathbb{N}}$, and conditions [\(iib\)](#page-39-1) and [\(iic\)](#page-39-2) of Theorem [4.12](#page-39-0) are fulfilled appears in [Bùi and Combettes](#page-130-5) [\(2020](#page-130-5)*b*, Theorem 4.2).

Theorem 11.1. Let $\alpha \in]0, +\infty[$, let $W: \mathcal{H} \to 2^{\mathcal{H}}$ be maximally monotone, let $C: \mathcal{H} \to \mathcal{H}$ be α -cocoercive and such that $Z = \text{zer}(W + C) \neq \emptyset$, let $x_0 \in \mathcal{H}$, and let $(\lambda_n)_{n \in \mathbb{N}}$ be a sequence in $]0, 2[$. Further, for every $n \in \mathbb{N}$, let $\widetilde{x}_n \in \mathcal{H}$ and let U_n : $\mathcal{H} \to \mathcal{H}$ be an operator such that ran $U_n \subset \text{ran}(U_n + W + C)$ and $U_n + W + C$ is injective. Iterate

for
$$
n = 0, 1, ...
$$

\n
$$
\begin{cases}\nw_n = J_{W+C}^{U_n} \tilde{x}_n \\
w_n^* = U_n \tilde{x}_n - U_n w_n - C w_n \\
q_n \in \mathcal{H} \\
t_n^* = w_n^* + C q_n \\
\delta_n = \langle x_n - w_n | t_n^* \rangle - ||w_n - q_n||^2 / (4\alpha) \\
d_n = \begin{cases}\n\frac{\delta_n}{||t_n^*||^2} t_n^*, & \text{if } \delta_n > 0, \\
0, & \text{otherwise}\n\end{cases}\n\end{cases}
$$
\n(11.4)

 \Box

Suppose that $\tilde{x}_n - x_n \to 0$. Then the conclusions of Theorem [4.12](#page-39-0) remain valid if the condition $U_n w_n - U_n x_n \to 0$ in [\(iic\)](#page-39-2) is replaced by $U_n w_n - U_n \tilde{x}_n \to 0$.

Proof. Adapt the pattern of the proof of Theorem [4.12.](#page-39-0)

Remark 11.2. The auxiliary sequence $(\widetilde{x}_n)_{n \in \mathbb{N}}$ in Theorem [11.1](#page-124-0) adds considerable breadth to the scope of the algorithm, compared to that of Theorem [4.12.](#page-39-0) Here are some illustrations of the condition $\tilde{x}_n - x_n \to 0$, where we assume that $\inf_{n \in \mathbb{N}} \lambda_n > 0$ and $\sup_{n \in \mathbb{N}} \lambda_n < 2$.

- (i) At iteration n, \tilde{x}_n can model an additive perturbation of x_n , say $\tilde{x}_n = x_n + e_n$. Here, the error sequence $(e_n)_{n\in\mathbb{N}}$ need only satisfy $||e_n|| \to 0$ and not the usual summability condition $\sum_{n\in\mathbb{N}} ||e_n|| < +\infty$ required in the quasi-Fejérian splitting methods of [Boţ and Hendrich](#page-129-3) [\(2013\)](#page-129-3), [Combettes](#page-132-3) [\(2001](#page-132-3)*b*, [2004,](#page-132-4) [2013](#page-132-0)*b*), [Combettes and Pesquet](#page-133-2) [\(2012\)](#page-133-2) and Vũ [\(2013\)](#page-144-2).
- (ii) In the spirit of inertial methods [\(Attouch and Cabot](#page-127-5) [2020,](#page-127-5) [Beck and Teboulle](#page-128-2) [2009](#page-128-2)*b*, [Chambolle and Dossal](#page-131-3) [2015,](#page-131-3) [Combettes and Glaudin](#page-132-7) [2017,](#page-132-7) [Polyak](#page-140-3) [1964\)](#page-140-3), let $(\alpha_n)_{n \in \mathbb{N}}$ be a sequence in R and set $(\forall n \in \mathbb{N} \setminus \{0\}) \widetilde{x}_n = x_n +$ $\alpha_n(x_n - x_{n-1})$. In these methods, $\alpha_n(x_n - x_{n-1}) \to 0$, which guarantees that $\|\widetilde{x}_n - x_n\| \to 0$, as required.
- (iii) More generally, weak convergence results can be derived from Theorem [11.1](#page-124-0) for iterations with memory, that is,

$$
(\forall n \in \mathbb{N}) \quad \widetilde{x}_n = \sum_{j=0}^n \mu_{n,j} x_j,
$$

where $(\mu_{n,j})_{0 \le j \le n} \in \mathbb{R}^{n+1}$ and $\sum_{j=0}^n \mu_{n,j} = 1.$ (11.5)

Here we have $\tilde{x}_n - x_n \to 0$ if $(1 - \mu_{n,n})x_n - \sum_{j=0}^{n-1} \mu_{n,j}x_j \to 0$. In the case of standard inertial methods, weak convergence requires more stringent conditions on the weights $(\mu_{n,j})_{n \in \mathbb{N}, 0 \le j \le n}$ [\(Combettes and Glaudin](#page-132-7) [2017\)](#page-132-7).

(iv) As indicated in Figure [11.1,](#page-123-0) Theorem [9.14](#page-114-0) on the Kuhn–Tucker projective splitting algorithm was derived from Proposition [4.10,](#page-38-1) hence from Theorem [4.8,](#page-35-0) and it does not appear possible to derive it from Theorem [4.12.](#page-39-0) However, as shown in [Bùi](#page-130-6) [\(2022](#page-130-6)*b*, Corollary 4), Theorem [9.14](#page-114-0) follows from Theorem [11.1](#page-124-0) (implemented with $C = 0$ and $q_n = w_n$) through a suitable choice of the auxiliary sequence $(\widetilde{x}_n)_{n\in\mathbb{N}}$. This last example provides further confirmation of the effectiveness of warped resolvents.

Acknowledgement

The author thanks Minh N. Bùi for his careful proofreading of the paper and his suggestions.
