

# EXHAUSTIVE OPERATORS AND VECTOR MEASURES

by N. J. KALTON

(Received 28th January 1974)

## 1. Introduction

Let  $S$  be a compact Hausdorff space and let  $\Phi: C(S) \rightarrow E$  be a linear operator defined on the space of real-valued continuous functions on  $S$  and taking values in a (real) topological vector space  $E$ . Then  $\Phi$  is called *exhaustive* (7) if given any sequence of functions  $f_n \in C(S)$  such that  $f_n \geq 0$  and

$$\sup_s \sum_{n=1}^{\infty} f_n(s) < \infty$$

then  $\Phi(f_n) \rightarrow 0$ . If  $E$  is complete then it was shown in (7) that exhaustive maps are precisely those which possess regular integral extensions to the space of bounded Borel functions on  $S$ ; this is equivalent to possessing a representation

$$\Phi(f) = \int_S f(s) d\mu(s)$$

where  $\mu$  is a regular countably additive  $E$ -valued measure defined on the  $\sigma$ -algebra of Borel subsets of  $S$ .

In this paper we seek conditions on  $E$  such that every continuous operator  $\Phi: C(S) \rightarrow E$  (for the norm topology on  $C(S)$ ) is exhaustive. If  $E$  is a Banach space then Pelczynski (14) has shown that every exhaustive map is weakly compact; then we have from results in (2) and (16);

**Theorem 1.1.** *If  $E$  is a Banach space containing no copy of  $c_0$ , then every bounded  $\Phi: C(S) \rightarrow E$  is exhaustive.*

**Theorem 1.2.** *If  $E$  is a Banach space containing no copy of  $l_\infty$ , then if  $S$  is  $\sigma$ -Stonian, every bounded  $\Phi: C(S) \rightarrow E$  is exhaustive.*

These results extend naturally to locally convex spaces, but here we study the general non-locally convex case. We show that Theorem 1.1 does indeed extend to arbitrary topological vector spaces; it seems likely that Theorem 1.2 extends also, but we here only prove special cases. In particular we prove Theorem 1.2 when  $E$  is separable (generalising a result due originally to Grothendieck (6)).

## 2. Operators on $c_0$

We denote by  $(e_n)$  the unit vector basis of  $c_0$ . If  $M \subset N$  is an infinite subset, then  $c_0(M)$  is the subspace of  $c_0$  of all sequences vanishing outside  $M$ . Let  $c_{00}$  represent the subspace of all sequences which are eventually zero, and let

$$A_n = \{t \in c_{00}: \|t\|_\infty \leq 1 \quad t_1 = t_2 = \dots = t_{n-1} = 0\}. \quad (n \geq 2)$$

Now let  $\Phi: c_0 \rightarrow (E, \tau)$  be a continuous linear operator mapping  $c_0$  into a metrisable topological vector space  $(E, \tau)$ . Let  $(U_n)$  be a base of closed balanced  $\tau$ -neighbourhoods of 0 satisfying  $U_{n+1} + U_{n+1} \subset U_n$  for  $n \geq 1$ . Define

$$V_n = \bigcap_{m=2}^{\infty} (U_n + \Phi(A_m)).$$

**Lemma 2.1.**  *$(V_n)$  is a base for a metrisable vector topology  $\gamma(\Phi)$  on  $E$ .*

**Proof.** Each  $V_n$  is balanced since each  $U_n$  and  $\Phi(A_m)$  is balanced. Since  $U_n$  is absorbent,  $V_n$  is absorbent. In view of Köthe (10, p. 146), it is necessary only to show that  $V_{n+1} + V_{n+1} \subset V_n$  for every  $n$ , in order to prove that  $(V_n)$  defines a vector topology.

Suppose  $x, y \in V_{n+1}$ ; then for any  $m$

$$x = u_1 + \Phi(t),$$

where  $u_1 \in U_{n+1}$  and  $t \in A_m$ . Since  $t \in c_{00}$ , there exists  $p$  such that  $t_i = 0$  for  $i \geq p$ . Then

$$y = u_2 + \Phi(t'),$$

where  $t' \in A_p$ . Thus

$$x + y = (u_1 + u_2) + \Phi(t + t')$$

and  $x + y \in U_n + \Phi(A_m)$ . Hence  $x + y \in V_n$ .

Now

$$\begin{aligned} \bigcap_{n=1}^{\infty} V_n &= \bigcap_{m=2}^{\infty} \bigcap_{n=1}^{\infty} (U_n + \Phi(A_m)) \\ &= \bigcap_{m=2}^{\infty} \overline{\Phi(A_m)} \quad (\text{closure in } \tau) \\ &\subset \overline{\Phi(A_2)}. \end{aligned}$$

However  $\bigcap_{n=1}^{\infty} V_n$  is a linear subspace of  $E$ , and, as  $\Phi$  is continuous,  $\overline{\Phi(A_2)}$  is bounded. Therefore

$$\bigcap_{n=1}^{\infty} V_n = \{0\},$$

and  $\gamma(\Phi)$  is Hausdorff.

**Lemma 2.2.** *If  $\{\Phi(e_n): n \in \mathbb{N}\}$  is not a  $\gamma(\Phi)$ -precompact set, then for some infinite subset  $M \subset \mathbb{N}$ ,  $\Phi: c_0(M) \rightarrow (E, \tau)$  is an isomorphism on to its image.*

**Proof.** We may find  $k \in \mathbb{N}$  such that for any  $\gamma(\Phi)$ -precompact subset  $S$  of  $E$ ,  $S + V_k$  does not contain  $\{\Phi(e_n): n \in \mathbb{N}\}$ . We then select by induction an increasing sequence of integers  $p(n)$  such that for every  $n$

$$(\alpha) \quad \Phi(e_{p(n)}) \notin V_k + T_{n-1} \quad n \geq 1$$

$$(\beta) \quad \Phi(e_{p(n)}) \notin U_{k+1} + T_{n-1} + \Phi(A_{p(n+1)}) \quad n \geq 1$$

where  $T_0 = \{0\}$  and for  $n \geq 1$

$$T_n = \left\{ \sum_{i=1}^n a_i \Phi(e_{p(i)}): |a_i| \leq 1 \right\}.$$

Pick  $p(1)$  so that  $(\alpha)$  holds. Now suppose  $p(1) \dots p(r)$  have been selected so that  $(\alpha)$  holds for  $1 \leq n \leq r$  and  $(\beta)$  holds for  $1 \leq n \leq r-1$ . Then by  $(\alpha)$

$$\Phi(e_{p(r)}) \notin V_k + T_{r-1}.$$

Since  $T_{r-1}$  is  $\tau$ -compact and symmetric we may have a finite symmetric subset  $\Sigma_{r-1}$  of  $T_{r-1}$  such that

$$T_{r-1} \subset \Sigma_{r-1} + U_{k+1}.$$

Now  $\Phi(e_{p(r)}) \notin V_k + \Sigma_{r-1}$ , and hence, for each  $\sigma \in \Sigma_{r-1}$  there is a  $q(\sigma)$  such that

$$\Phi(e_{p(r)}) \notin \sigma + U_k + \Phi(A_{q(\sigma)}).$$

Thus there is a  $q = \max \{q(\sigma) : \sigma \in \Sigma_{r-1}\}$  such that

$$\Phi(e_{p(r)}) \notin \Sigma_{r-1} + U_k + \Phi(A_q).$$

Since  $T_{r-1} \subset \Sigma_{r-1} + U_{k+1}$  we conclude that

$$\Phi(e_{p(r)}) \notin T_{r-1} + U_{k+1} + \Phi(A_q).$$

Now pick  $p(r+1) > \max \{p(r), q\}$  to satisfy  $(\alpha)$ , using the fact that  $T_r$  is  $\gamma(\Phi)$ -compact. This completes the inductive construction.

Suppose  $(a_i, \dots, a_n)$  is a sequence with  $\max_{1 \leq i \leq n} |a_i| = |a_j| = 1$ . Then

$$a_j \Phi(e_{p(j)}) = \sum_{i=1}^n a_i \Phi(e_{p(i)}) - \sum_{i=1}^{j-1} a_i \Phi(e_{p(i)}) - \sum_{i=j+1}^n a_i \Phi(e_{p(i)})$$

(a summation over the empty set is taken to be zero), and therefore

$$a_j \Phi(e_{p(j)}) \in \sum_{i=1}^n a_i \Phi(e_{p(i)}) + T_{j-1} + \Phi(A_{p(j+1)}).$$

Hence by  $(\beta)$

$$\sum_{i=1}^n a_i \Phi(e_{p(i)}) \notin U_{k+1}.$$

Let  $M = \{p(1), p(2), \dots\}$  and consider  $\Phi: c_{00} \cap c_0(M) \rightarrow (E, \tau)$ . If  $\Phi(t^{(n)}) \rightarrow 0$  and  $\|t^{(n)}\|_\infty \geq \varepsilon > 0$  for all  $n$ , then  $\Phi(\|t^{(n)}\|_\infty^{-1} t^{(n)}) \rightarrow 0$ . However

$$\Phi(\|t^{(n)}\|_\infty^{-1} t^{(n)}) \notin U_{k+1}$$

for all  $n$ , and so we have a contradiction. Therefore if  $\Phi(t^n) \rightarrow 0$  then

$$\|t^{(n)}\|_\infty \rightarrow 0$$

and  $\Phi$  is an isomorphism. Clearly  $\Phi$  is also an isomorphism on the closure of  $c_{00} \cap c_0(M)$ , i.e.  $c_0(M)$ .

Note that, since  $\Phi$  is continuous  $\{\sum_{n \in K} \phi(e_n) : K \subset \mathbb{N}, K \text{ finite}\}$  is  $\gamma(\Phi)$ -bounded.

Therefore if  $\{\Phi(e_n) : n \in \mathbb{N}\}$  is  $\gamma(\Phi)$ -precompact then  $\Phi(e_n) \rightarrow 0$  in  $\gamma(\Phi)$ .

**Theorem 2.3.** *Suppose  $(E, \tau)$  is a topological vector space and  $\Phi: c_0 \rightarrow E$  is a continuous linear map; then either*

- (i)  $\Phi(e_n) \rightarrow 0(\tau)$ ,

or

(ii) there is an infinite subset  $M$  of  $\mathbb{N}$  such that  $\Phi: c_0(M) \rightarrow E$  is an isomorphism onto its image.

**Proof.** Suppose neither (i) nor (ii) holds. Then we may find a metrisable topological vector space  $(F, \mu)$  and a continuous linear map  $\Psi: E \rightarrow F$  such that (i) does not hold for  $\Psi\Phi$ . Then (ii) also must fail for  $\Psi\Phi$ , and so we may reduce consideration to the metrisable case for  $\tau$ . We may also suppose that  $(E, \tau)$  is complete. As above, let  $(U_n)$  be a base of neighbourhoods for  $\tau$ .

Now by Lemma 2.2,  $\Phi(e_n) \rightarrow 0$   $\gamma(\Phi)$ . Let  $\bar{\gamma}$  be the finest vector topology such that  $\bar{\gamma} \leq \tau$  and  $\Phi(e_n) \rightarrow 0$   $\bar{\gamma}$  ( $\bar{\gamma}$  is given by all  $\tau$ -continuous  $F$ -semi-norms which make  $\Phi(e_n)$  a null sequence). Then  $\bar{\gamma}$  is Hausdorff since  $\gamma(\Phi)$  is Hausdorff. Now let  $\tilde{\gamma}$  be the metrisable topology with a base of neighbourhoods  $(\bar{U}_n)$  (closure in  $\bar{\gamma}$ ). Then if  $\bar{\gamma} = \tilde{\gamma}$  the identity map in  $i: (E, \bar{\gamma}) \rightarrow (E, \tau)$  is almost continuous and therefore by the Closed Graph Theorem (Kelley (9), p. 213),  $\bar{\gamma} = \tau$ . Since we are assuming (i) to be false we conclude that  $\bar{\gamma} < \tilde{\gamma} \leq \tau$ . Therefore

$$\Phi(e_n) \not\rightarrow 0(\bar{\gamma})$$

and so by Theorem 3.2 of (8), there is a subsequence  $(\Phi(e_n): n \in M)$  which is a regular basic sequence in  $(E, \bar{\gamma})$ . (A sequence is regular if it is bounded away from zero and basic if it forms a basis for its closed linear span in the completion of  $(E, \bar{\gamma})$ .)

Now if  $t \in c_0(M)$  then  $\sum t_n \Phi(e_n)$  converges in  $(E, \tau)$  and hence in  $(E, \bar{\gamma})$ . Then as  $(\Phi(e_n): n \in M)$  is  $\bar{\gamma}$ -regular it is equivalent to the unit vector basis of  $c_0$ . By a result of Arsove and Edwards (1),  $\Phi: c_0(M) \rightarrow G$  is an isomorphism where  $G$  is the closed linear span of  $\Phi(e_n)$  in  $(E, \bar{\gamma})$ . Then  $G$  is also closed in  $(E, \tau)$  and by the Open Mapping Theorem  $\Phi$  is also an isomorphism for the topology  $\tau$ . This contradicts our assumption that (ii) was false.

**Theorem 2.4.** Let  $(E, \tau)$  be a topological vector space containing no copy of  $c_0$ . Then any bounded linear map  $\Phi: c_0 \rightarrow E$  takes the unit ball  $B$  of  $c_0$  into a precompact subset of  $E$ .

**Proof.** If  $\Phi(B)$  is not precompact, we may find a neighbourhood  $U$  of zero in  $E$  and a sequence  $t^{(n)}$  in  $c_{00} \cap B$  such that  $\Phi(t^{(n)}) - \Phi(t^{(m)}) \notin U$  for  $n \neq m$ .

By selecting a subsequence we may suppose  $(t^{(n)})$  is co-ordinatewise convergent in  $l_\infty$ . Thus  $t^{(n)} - t^{(n+1)} \rightarrow 0$  co-ordinatewise. We may then select a subsequence  $s^{(n)}$  of  $(t^{(n)} - t^{(n+1)})$  which is disjoint (i.e. if  $n \neq m$   $s_k^{(n)} \cdot s_k^{(m)} = 0$  for all  $k$ ). Define  $\Psi: c_0 \rightarrow E$  by

$$\Psi(u) = \sum_{i=1}^{\infty} u_i \Psi(s^{(i)}).$$

As  $\Psi(s^{(n)}) \notin U$ , we may conclude from Theorem 2.3 that  $E$  contains a subspace isomorphic to  $c_0$ .

If  $E$  is complete then the hypotheses of Theorem 2.4 ensure that  $\sum_{n=1}^{\infty} \Phi(e_n)$  converges.

3. Operators on  $l_\infty$

**Lemma 3.1.** *Let  $E$  be a separable metrisable topological vector space and suppose  $\Phi: l_\infty \rightarrow E$  is a continuous operator such that  $\Phi(c_0) = 0$ . Then there is an infinite subset  $M$  of  $N$  such that  $\Phi(l_\infty(M)) = 0$ .*

Here  $l_\infty(M) = \{t \in l_\infty: t_i = 0, i \notin M\}$ .

**Proof.** We may assume that  $E$  is complete. Let  $(M_\alpha: \alpha \in \mathcal{A})$  be an uncountable collection of infinite subsets of  $N$  such that  $M_\alpha \cap M_\beta$  is finite for each  $\alpha \neq \beta$ , see (19). Suppose if possible that for each  $\alpha \in \mathcal{A}$  there exists  $t^{(\alpha)} \in l_\infty(M_\alpha)$  with  $\|t^{(\alpha)}\|_\infty = 1$  and  $\Phi(t^{(\alpha)}) \neq 0$ . Let  $\mathcal{A}_k = \{\alpha: \Phi(t^{(\alpha)}) \notin V_k\}$  where  $(V_k)$  is a base of neighbourhoods of 0 in  $E$ . Then for some  $k$ ,  $\mathcal{A}_k$  is uncountable; however  $(\Phi(t^{(\alpha)}): \alpha \in \mathcal{A}_k)$  is separable and hence there is a sequence  $(\alpha_n)$  in  $\mathcal{A}_k$  such that

$$\Phi(t^{(\alpha_n)}) \rightarrow x_0,$$

where  $x_0 \neq 0$ . Then for any  $p$

$$\Phi\left(\sum_{n+1}^{n+p} t^{(\alpha_i)}\right) \rightarrow px_0.$$

However since  $M_{\alpha_i} \cap M_{\alpha_j}$  is finite if  $i \neq j$  and  $\Phi(c_0) = 0$  we conclude that

$$\Phi\left(\sum_{n+1}^{n+p} t^{(\alpha_i)}\right) \in \Phi(B),$$

where  $B$  is the unit ball of  $l_\infty$ . Thus  $px_0 \in \overline{\Phi(B)}$  for any  $p$  and we have a contradiction.

**Theorem 3.2.** *Let  $(E, \tau)$  be a separable topological vector space, and let  $\Phi: l_\infty \rightarrow E$  be a continuous linear operator. Then  $\Phi(e_n) \rightarrow 0$ .*

**Proof.** Since  $E$  may be embedded in a product of separable metrisable spaces, it is sufficient to assume that  $(E, \tau)$  is metrisable and complete. Now suppose  $\Phi(e_n) \rightarrow 0$  in  $(E, \tau)$ . Then there is an infinite subset  $M$  of  $N$  such that  $\Phi: c_0(M) \rightarrow (E, \tau)$  is an isomorphism onto a closed subspace  $G$  of  $E$ .

Let  $\pi: E \rightarrow E/G$  be the quotient map; then  $\pi\Phi = 0$  on  $c_0(M)$  and by Lemma 3.1 there is an infinite subset  $M_0$  of  $M$  such that  $\pi\Phi = 0$  on  $l_\infty(M_0)$ , i.e.  $\Phi(l_\infty(M_0)) \subset G$ . Now as  $G \cong c_0$ , we may apply the theorem of Grothendieck (6, p. 173), or Rosenthal (16) to deduce  $\Phi$  is weakly compact on  $l_\infty(M_0)$  and hence  $\sum_{n \in M_0} \Phi(e_n)$  is weakly subseries convergent in  $G$ . By the Orlicz-Pettis Theorem  $\Phi(e_n) \rightarrow 0$  (see e.g. (5) p. 318, (12) or (15)).

It is very possible Theorem 3.2 can be extended to topological vector spaces containing no copy of  $l_\infty$ . However, here we have only a partial result. The technique of the following theorem is essentially found in Drewnowski (4). We identify  $l_\infty$  as  $C(\beta N)$  and thus we can define exhaustive operators as in the introduction.

**Theorem 3.3.** *Let  $\Phi: l_\infty \rightarrow (E, \tau)$  be a continuous linear operator, and suppose there is a Hausdorff vector topology  $\rho$  on  $E$  such (i)  $\Phi: l_\infty \rightarrow (E, \rho)$  is exhaustive (ii)*

$\tau$  is  $\rho$ -polar, i.e. has a base of  $\rho$ -closed neighbourhoods of  $\theta$ . Then if  $\Phi(e_n) \rightarrow 0$  in  $\tau$ , there is an infinite subset  $M$  of  $\mathbb{N}$  such that  $\Phi: l_\infty(M) \rightarrow (E, \tau)$  is an isomorphism onto its image.

**Proof.** By (8) Proposition 2.1, there is a  $\tau$ -continuous  $F$ -semi-norm  $\eta$  of the form

$$\eta(x) = \sup (\lambda(x): \lambda \in \Lambda)$$

where  $\Lambda$  is a collection of  $\rho$ -continuous  $F$ -semi-norms and such that for an infinite subset  $M_0$  of  $\mathbb{N}$

$$\eta(\Phi(e_n)) \geq 1 \quad n \in M_0.$$

By Theorem 2.3 we may suppose that for some subsequence  $M_1$  of  $M_0$ ,  $\Phi: c_0(M_1) \rightarrow (\hat{E}, \eta_1)$  is an embedding (where  $(\hat{E}, \eta_1)$  is the Hausdorff quotient of  $(E, \eta)$ ). Thus if  $t \in c_0(M_1), \|t\|_\infty = 1$  then

$$\eta(\Phi(t)) \geq \theta > 0.$$

We next select a sequence  $(m_k: k = 1, 2, \dots)$  in  $\mathbb{N}$  and a sequence

$$(M_k: k = 1, 2, \dots)$$

of infinite subsets of  $\mathbb{N}$  by induction. First choose  $m_1 \in M_1$ . Next given  $(m_1, \dots, m_k)$  and  $(M_1, \dots, M_k)$  let  $S_k$  be a finite subset of

$$L_k = \left\{ \sum_{i=1}^k t_i \Phi(e_{m_i}): \max |t_i| = 1 \right\}$$

such that for  $x \in L_k$  there exists  $s \in S_k$  with

$$\eta(x-s) \leq \frac{1}{8}\theta.$$

For each  $s \in S_k$  pick  $\lambda_s \in \Lambda$  such that

$$\lambda_s(s) \geq \eta(s) - \frac{1}{8}\theta.$$

Now let  $M_k = \bigcup_{n=1}^\infty P_n$  where  $(P_n)$  is any sequence of disjoint infinite sets. Since  $\Phi$  is exhaustive for  $\rho$  we may find  $n_0$  such that for  $t \in l_\infty(P_{n_0}), \|t\|_\infty \leq 1$  and  $s \in S_k$

$$\lambda_s(\Phi(t)) \leq \frac{1}{8}\theta.$$

Let  $M_{k+1} = P_{n_0}$  and then choose  $m_{k+1} \in M_{k+1}$ . This constructs a set

$$M = (m_1, m_2, \dots, m_k, \dots)$$

such that  $(m_{k+1}, m_{k+2}, \dots) \subset M_{k+1}$  for all  $k$ .

Now suppose  $t \in l_\infty(M)$  with  $\|t\|_\infty = 1$ . For  $\varepsilon > 0$  there exists  $k$  such that  $|t_{m_k}| > 1 - \varepsilon$ ; thus there exists  $\delta$  with  $|\delta| < \varepsilon$  and such that if  $t' = t + \delta e_{m_k}$  then  $\|t'\| = |t'_{m_k}| = 1$ . Then let  $t'' = \sum_{i=1}^k t'_i e_{m_i}$  and choose  $s \in S_k$  such that

$$\eta(\Phi(t'') - s) \leq \theta \frac{1}{8}.$$

Then

$$\begin{aligned} \eta(\Phi(t')) &\geq \lambda_s(\Phi(t')) \\ &\geq \lambda_s(\Phi(t'')) - \frac{1}{8}\theta \\ &\geq \lambda_s(s) - \frac{1}{4}\theta \\ &\geq \eta(s) - \frac{3}{8}\theta \\ &\geq \frac{5}{8}\theta. \end{aligned}$$

Hence

$$\eta(\Phi(t)) \geq \frac{5}{8}\theta - \eta(\varepsilon\Phi(e_{m_k})),$$

and therefore, as  $\varepsilon > 0$  is arbitrary and  $(\Phi(e_n) : n \in \mathbb{N})$  is bounded,

$$\eta(\Phi(t)) \geq \frac{5}{8}\theta.$$

It follows easily that  $\Phi$  is an isomorphism on  $l_\infty(M)$ .

#### 4. Applications

In this section we collect together the main results of the paper, which are deductions from the more technical results of Sections 2 and 3.

**Theorem 4.1.** *Let  $E$  be a topological vector space containing no copy of  $c_0$ ; then every continuous linear operator  $\Phi : C(S) \rightarrow E$ , where  $S$  is compact Hausdorff, is exhaustive (and can therefore be represented in the form*

$$\Phi(f) = \int_S f(s) d\mu,$$

where  $\mu$  is a regular countably additive  $E$ -valued vector measure defined on the Borel sets of  $S$ ).

**Proof.** Let  $(f_n)$  be any sequence of positive functions in  $C(S)$  such that

$$\sup_s \sum_{n=1}^\infty f_n(s) < \infty.$$

Then we can define  $\Psi : c_0 \rightarrow E$  by

$$\Psi(t) = \Phi\left(\sum_{n=1}^\infty t_n f_n\right)$$

$\left(\sum_{n=1}^\infty t_n f_n\right)$  converges in the norm topology of  $C(S)$ ). By Theorem 2.3  $\Psi(e_n) \rightarrow 0$

i.e.  $\Phi(f_n) \rightarrow 0$  and so  $\Phi$  is exhaustive.

**Theorem 4.2.** *Suppose  $S$  is a  $\sigma$ -Stonian compact Hausdorff space and that  $E$  is a separable topological vector space. Then any continuous linear operator  $\Phi : C(S) \rightarrow E$  is exhaustive.*

**Proof.** Suppose  $f_n \in C(S)$ ,  $f_n \geq 0$  and

$$\sup_s \sum_{n=1}^\infty f_n(s) < \infty.$$

Then since  $C(S)$  is  $\sigma$ -order-complete we can define for  $t \in l_\infty$  and  $t \geq 0$  the order-sum  $o - \sum_{n=1}^\infty t_n f_n = \sup_n \sum_{k=1}^n t_k f_k$ . We can extend this definition to a linear map  $\Gamma: l_\infty \rightarrow C(S)$  and  $\Gamma$  is continuous. Now let  $\Psi = \Gamma\Phi$  and apply Theorem 3.2.

**Theorem 4.3.** *Suppose  $(E, \tau)$  is an  $F$ -space containing no copy of  $l_\infty$  and  $\Phi: C(S) \rightarrow E$  is a continuous linear operator which is exhaustive for a weaker Hausdorff vector topology  $\rho$  on  $E$ . Then  $\Phi$  is exhaustive for  $\tau$ .*

**Proof.** Let  $\gamma$  be the largest vector topology on  $E$  such that  $\gamma \leq \tau$  and  $\Phi$  is  $\gamma$ -exhaustive. Let  $\bar{\gamma}$  be the topology with a base of  $\tau$ -neighbourhoods consisting of the  $\gamma$ -closures of  $\tau$ -neighbourhoods of 0.

Suppose now for some  $f_n \geq 0$  with  $\sup \sum_n f_n(s) < \infty$  that  $\Phi(f_n) \rightarrow 0(\bar{\gamma})$ . Then we may form the map  $\Psi: l_\infty \rightarrow E$  as in Theorem 4.2 and by Theorem 3.3 there is infinite subset  $M$  of  $\mathbb{N}$  such that  $\Psi: l_\infty(M) \rightarrow (E, \bar{\gamma})$  is an embedding. Hence  $\Psi: l_\infty(M) \rightarrow (E, \tau)$  is an embedding and this contradicts the hypotheses of the theorem. Hence  $\Phi(f_n) \rightarrow 0(\bar{\gamma})$  and so  $\Phi$  is  $\bar{\gamma}$ -exhaustive. However,  $\bar{\gamma} \leq \tau$  and therefore  $\bar{\gamma} \leq \gamma$ ; thus the identity  $I: (E, \bar{\gamma}) \rightarrow (E, \tau)$  is almost continuous and by the Closed Graph Theorem (Kelley (9), p. 213) is also continuous, i.e.  $\gamma = \tau$  and  $\Phi$  is  $\tau$ -exhaustive.

**Remark.** If  $E$  has the property that the continuous linear operators with separable range separate points then a topology  $\rho$  can also be found to satisfy the conditions of Theorem 4.3.

Next we mention two other applications. Our first result generalises a theorem of Diestel (3).

**Theorem 4.4.** *Let  $E$  be a separable locally bounded  $F$ -space, and let  $\mathcal{S}$  be a  $\sigma$ -algebra of subsets of a set  $S$ . Let  $\mu: \mathcal{S} \rightarrow E$  be a bounded (finitely-additive) measure. Then  $\mu$  is exhaustive.*

**Note.** A measure  $\mu$  is called exhaustive or strongly bounded if for any sequence  $(S_n)$  of disjoint sets  $\mu(S_n) \rightarrow 0$ .

**Proof.** Since  $E$  is locally bounded, the topology may be given by a  $p$ -norm  $\| \cdot \|$  where  $0 < p \leq 1$ . Let

$$\sup_{S \in \mathcal{S}} \| \mu(S) \| = \theta.$$

We use a technique due to Robertson (15);  $\mu$  may be extended to a linear map  $\Phi_0$  on the simple functions  $\Sigma(\mathcal{S})$  on  $\mathcal{S}$ . Then  $\Sigma(\mathcal{S})$  is a normed space under

$$\| f \| = \sup_{s \in S} | f(s) |;$$

suppose  $f \in \Sigma(\mathcal{S})$  and  $\| f \|_\infty \leq 1$ . Then

$$\Phi_0(f) = \sum_{i=1}^\infty 2^{-i} (\mu(S_i) - \mu(T_i))$$

where  $S_i, T_i \in \mathcal{S}$  (only finitely many of  $S_i, T_i$  are distinct). Then

$$\|\Phi_0(f)\| \leq 2\theta \sum_{i=1}^{\infty} 2^{-ip} \leq \frac{\theta 2^{1+p}}{1-2^{-p}}.$$

Thus  $\Phi_0: \Sigma(\mathcal{S}) \rightarrow E$  is continuous and extends to a continuous operator  $\Phi: B(\mathcal{S}) \rightarrow E$  where  $B(\mathcal{S})$  is the space of bounded  $\mathcal{S}$ -measurable functions on  $S$ . Using the techniques of Theorem 4.2 it follows that if  $(S_n)$  is a disjoint sequence in  $\mathcal{S}$ ,  $\mu(S_n) = \Phi(\chi_{S_n}) \rightarrow 0$  where  $\chi_{S_n}$  is the characteristic of  $S_n$ . (Alternatively  $B(\mathcal{S})$  is isometrically isomorphic to  $C(T)$  where  $T$  is  $\sigma$ -Stonian.)

Clearly the preceding theorem generalises to semi-convex topological vector spaces (i.e. spaces which can be embedded in a product of locally bounded spaces).

A  $C$ -series is a sequence  $x_n$  in a topological vector space such that  $\sum t_n x_n$  converges whenever  $t_n \rightarrow 0$ . If  $E$  is a space such that every  $C$ -series converges, then  $E$  is called a  $C$ -space (Schwartz (17), Thomas (18)). Clearly Theorem 2.3 yields

**Theorem 4.4.** *A complete topological vector space is a  $C$ -space if and only if it contains no subspace isomorphic to  $c_0$ .*

A topological vector space is said to have property (O) (Orlicz (13), Labuda (10)) if every series  $\sum x_n$  in  $E$  such that the set  $\left\{ \sum_{n \in \Delta} x_n : \Delta \subset \mathbb{N}, \Delta \text{ finite} \right\}$  is bounded, is also convergent. Again by Theorem 2.3 and a similar argument to Theorem 4.3 we conclude

**Theorem 4.5.** *A complete semi-convex topological vector space  $E$  has property (O) if and only if  $E$  contains no subspace isomorphic to  $c_0$ .*
