Received 12 May 1997; accepted in final form 17 June 1997

**Abstract.** In this paper, we study an exceptional theta correspondence, obtained by restricting the minimal automorphic representation of the adjoint group of type  $E_7$  and rank 3 over  $\mathbb{Q}$  to the dual pair  $G \times PGS p_6$ . Here  $G$  is the anisotropic form of  $G_2$  over  $\mathbb{Q}$ ; using the correspondence, we lift certain automorphic forms on  $G$  to holomorphic cusp forms on  $PGSp_6$ . This lifting provides the first step in a project to construct motives of rank 7 and weight 0 over  $\mathbb{Q}$  with Galois group of type  $G_2$ .

**Mathematics Subject Classifications (1991).** F27, F70, G18.

**Key words:** Exceptional theta correspondence, modular forms, motives.

### Introduction

Serre has asked if there are motives  $M$  with motivic Galois group of type  $G_2$  [Se3; pg 386]. This paper is the first step in a project to construct such a motive  $M$ , of rank 7 and weight 0, over the base field  $\mathbb{Q}$ .

Let  $G$  be the anisotropic form of  $G_2$  over  $\mathbb{Q}$ , and let  $\pi = \hat{\otimes}_v \pi_v$  be an automorphic representation of the adelic group  $G(\mathbb{A})$ . At almost all primes  $p$ , the local representation  $\pi_p$  is unramified and has Satake parameter  $s_p$ , a semi-simple conjugacy class in the dual group  $\hat{G}(\mathbb{C}) = G_2(\mathbb{C})$ . Let  $\hat{V}$  be the irreducible 7-dimensional representation of  $\hat{G}(\mathbb{C})$ . The unramified representation  $\pi_p$  is determined by the characteristic polynomial of  $s_p$  on  $\hat{V}$ :

$$L(\pi_p, \hat{V}, X) = \det(1 - s_p X | \hat{V})^{-1}.$$

By giving a rational structure on the space of modular forms for  $G$ , we show that the coefficients of all the polynomials  $\det(1 - s_p X | \hat{V})$  lie in a totally real number field  $E \subset \mathbb{C}$ . Under the additional hypothesis that at least one local component of  $\pi$  is the Steinberg representation, we conjecture the existence of a motive  $M = M(\pi)$  of weight 0 over  $\mathbb{Q}$  with coefficients in  $E$ , whose local  $L$ -function at unramified primes  $p$  is given by the formula

$$L_p(M, s) = L(\pi_p, \hat{V}, p^{-s}).$$

The first step in our construction of  $M$  is to lift  $\pi$  to an automorphic, cuspidal representation  $\pi'$  of the split group  $G' = PGSp_6$ . Such a lifting, at least at the level of  $L$ -packets, is predicted by Langlands functoriality. Indeed, we have an inclusion of dual groups

$$\hat{G}(\mathbb{C}) = G_2(\mathbb{C}) \hookrightarrow \mathrm{Spin}_7(\mathbb{C}) = \hat{G}'(\mathbb{C})$$

which realizes  $G_2$  as the stabilizer of a non-isotropic vector in the 8-dimensional spin representation of  $\mathrm{Spin}_7$ . We are able to construct a lifting  $\pi \rightarrow \pi'$  with the property predicted by functoriality in many cases, using an exceptional theta-correspondence. The group  $G \times G'$  appears as a dual pair in the adjoint group  $H$  of type  $E_7$  and rank 3 over  $\mathbb{Q}$ .

The bulk of this paper is devoted to a study of the theta-correspondence which results from the restriction of the minimal representation of  $H$  to the subgroup  $G \times G'$ . The local results were suggested by the work of Huang, Pandžić, and Savin [HPS] on the quaternionic form of  $E_7$  of rank 4 over  $\mathbb{R}$ . The global results on cuspidality and non-vanishing were inspired by the work of Ginzburg, Rallis, and Soudry [GRS2] in the split case.

The second step in our construction of  $M$  is to use the lifted representation  $\pi'$  of  $G'$  to define a motive  $M'$  in the cohomology of a Siegel modular variety. Specifically, assume that there is a finite, non-empty set  $S$  of primes such that  $\pi_p$  is unramified for all  $p \notin S$ , and  $\pi_p$  is the Steinberg representation for all  $p \in S$ . Let  $X$  be the 6-dimensional Siegel modular variety over  $\mathbb{Q}$ , classifying principally polarized abelian varieties of dimension 3 with an Iwahori level structure at all  $p \in S$ . If  $\pi_\infty$  has highest weight  $k_1\omega_1 + k_2\omega_2$ , where  $\omega_1$  is the weight of the 7-dimensional representation and  $\omega_2$  is the weight of the 14-dimensional adjoint representation, let  $\mathcal{F}$  be the local system on  $X$  corresponding to the rational representation of  $G'$  with highest weight  $(k_1 + 2k_2, k_1 + k_2, k_2)$ . Then the  $\pi'_f$ -isotypic component  $M' \subseteq H_c^6(X, \mathcal{F})(3)$  should have rank 8 and coefficients in  $E$ . As  $\pi'$  is lifted from  $G$ ,  $M'$  should decompose as the sum of  $M$  and a Hodge class, arising from Hilbert modular 3-folds in  $X$ . Several difficulties remain in proving this, but we hope to treat these geometric questions in a future paper.

## 1. Spaces of modular forms

In this chapter we develop the arithmetic theory of modular forms for semi-simple groups over  $\mathbb{Q}$  with  $G(\mathbb{R})$  compact. At the end of this chapter we specialize to the case when  $G$  is of type  $G_2$ . In particular, we construct two interesting modular forms for the anisotropic form of  $G_2$ . It will be shown in Chapter 5, that they lift non-trivially to  $G' = PGSp_6$ .

### 1. Groups

Let  $G$  be a semi-simple algebraic group over  $\mathbb{Q}$  with  $G(\mathbb{R})$  compact. To simplify some of the exposition, we will further assume that  $G$  is simply connected, and is

an inner form of a split group over  $\mathbb{Q}$ . Then  $G$  is split over  $\mathbb{Q}_p$  for almost all primes  $p$ , and  $-1$  is an element of the Weyl group of  $G$ . Also, the center  $Z(G)$  is killed by 2.

Let  $W$  be an irreducible algebraic representation of  $G$  over  $\mathbb{Q}$  which is absolutely irreducible (i.e. remains irreducible over  $\bar{\mathbb{Q}}$ ). Then  $W$  is orthogonal, and the  $G$ -invariant symmetric bilinear form on  $W$  is definite over  $\mathbb{R}$ . We fix a  $G$ -invariant, positive-definite inner product

$$\langle \cdot, \cdot \rangle : W \times W \rightarrow \mathbb{Q}, \tag{1.1}$$

which is unique up to scaling by  $\mathbb{Q}^+$ .

2. *Modular forms*

Let  $\hat{\mathbb{Q}} = \mathbb{Q} \otimes \hat{\mathbb{Z}}$  be the ring of finite adèles of  $\mathbb{Q}$ , so  $\mathbb{A} = \mathbb{R} \times \hat{\mathbb{Q}}$  is the ring of adèles. Let  $K$  be an open compact subgroup of the locally compact group  $G(\hat{\mathbb{Q}})$ . Since  $G(\mathbb{Q}) \backslash G(\hat{\mathbb{Q}})$  is compact ([B2]), the double coset space

$$G(\mathbb{Q}) \backslash G(\hat{\mathbb{Q}}) / K \tag{2.1}$$

is finite. Let  $\{g_\alpha\}$  represent the distinct double cosets, and for each  $\alpha$ , define the finite group

$$\begin{aligned} \Gamma_\alpha &= G(\mathbb{Q}) \cap g_\alpha K g_\alpha^{-1} \\ &= \{\gamma \in G(\mathbb{Q}) \mid \gamma g_\alpha K = g_\alpha K\}. \end{aligned} \tag{2.2}$$

Associated to  $K \subset G(\hat{\mathbb{Q}})$  and an irreducible representation  $W$  of  $G$  over  $\mathbb{Q}$ , we have a rational vector space

$$\begin{aligned} A &= A(K, W) \\ &= \{F : G(\hat{\mathbb{Q}}) / K \rightarrow W \mid F(\gamma g) = \gamma F(g), \text{ all } \gamma \in G(\mathbb{Q})\}. \end{aligned} \tag{2.3}$$

This is the space of modular forms of ‘level  $K$ ’ and ‘weight  $W$ ’ for  $G$ .

A function  $F$  in  $A$  is clearly determined by the values  $F(g_\alpha)$  on the double coset representatives, and  $F(g_\alpha)$  lies in the subspace of  $W$  fixed by  $\Gamma_\alpha$ . This observation gives a proof of the following.

**PROPOSITION 2.3.** *The space  $A$  is finite-dimensional and the map taking  $F$  to the elements  $F(g_\alpha)$  in  $W^{\Gamma_\alpha}$  is a linear isomorphism  $A \cong \bigoplus_\alpha W^{\Gamma_\alpha}$ .*

We can use the proposition to define an inner product on  $A$  with values in  $\mathbb{Q}$ , by the formula

$$\langle F, F' \rangle_A = \sum_\alpha w_\alpha^{-1} \langle F(g_\alpha), F'(g_\alpha) \rangle, \tag{2.4}$$

where  $w_\alpha = \text{Card}(\Gamma_\alpha)$ . This is independent of the choice of coset representatives, as the pairing  $\langle, \rangle$  on  $W$  is  $G(\mathbb{Q})$ -invariant.

### 3. Hecke operators

The Hecke algebra of  $K$  is the convolution algebra of locally constant, compactly supported functions

$$\begin{aligned} \mathcal{H}_K &= \mathcal{H}(G(\hat{\mathbb{Q}})/K) \\ &= \{f: K \backslash G(\hat{\mathbb{Q}})/K \rightarrow \mathbb{Q}\} \end{aligned} \quad (3.1)$$

using Haar measure giving  $K$  volume 1. This has, as additive basis, the characteristic functions  $\text{char}(KtK)$  of double cosets, and acts  $\mathbb{Q}$ -linearly on  $A$  as follows. Let  $F \in A$ . Writing

$$KtK = \cup_i t_i K, \quad (3.2)$$

where the number of single cosets is finite, we have the formula

$$\text{char}(KtK)|F(g) = \sum_i F(gt_i). \quad (3.3)$$

The following adjoint formula shows that  $A$  is a semi-simple  $\mathcal{H}_K$ -module.

PROPOSITION 3.4.

$$\langle \text{char}(KtK)|F, F' \rangle_A = \langle F, \text{char}(Kt^{-1}K)|F' \rangle_A. \quad (3.5)$$

*Proof.* This is standard. See, for example, [Shm].

Over the algebraically closed field  $\mathbb{C}$ , the isotypic decomposition of  $A \otimes \mathbb{C}$  as an  $\mathcal{H}_K \otimes \mathbb{C}$  module is given by the theory of automorphic forms. Let  $m$  be an element in

$$\text{Hom}_{G(\mathbb{R})}(W \otimes \mathbb{C}, L^2(G(\mathbb{Q}) \backslash G(\mathbb{A})/K)). \quad (3.6)$$

If  $w$  is an element in  $W \otimes \mathbb{C}$ , the function  $m_w = m(w)$  is smooth. In particular, for any  $g$  in  $G(\mathbb{A})$ , the complex number  $m_w(g)$  is well defined. We define an element  $F = F(m)$  in  $A \otimes \mathbb{C}$  by the formula

$$\langle F(g_f), w \rangle = m_w(1 \times g_f), \quad (3.7)$$

where  $g_f$  is in  $G(\hat{\mathbb{Q}})$ .

PROPOSITION 3.7. *The map  $m \mapsto F(m)$  gives a linear isomorphism of  $\mathcal{H}_K \otimes \mathbb{C}$ -modules*

$$\text{Hom}_{G(\mathbb{R})}(W \otimes \mathbb{C}, L^2(G(\mathbb{Q}) \backslash G(\mathbb{A})/K)) \cong A \otimes \mathbb{C}.$$

*Proof.* We construct an inverse map. Let  $F$  be in  $A \otimes \mathbb{C}$ . If  $g$  is an element in  $G(\mathbb{A})$ , write  $g = g_\infty \times g_f$  where  $g_f$  is in  $G(\mathbb{R})$ , and  $g_f$  is in  $G(\hat{\mathbb{Q}})$ . We define an element  $m = m(F)$  in  $\text{Hom}_{G(\mathbb{R})}(W \otimes \mathbb{C}, L^2(G(\mathbb{Q}) \backslash G(\mathbb{A})/K))$  by the formula

$$m_w(g) = \langle g_\infty w, F(g_f) \rangle.$$

The map  $F \mapsto m(F)$  is the inverse of the map  $m \mapsto F(m)$ .

#### 4. Spherical operators

Assume that  $K = \prod K_p$  in  $G(\hat{\mathbb{Q}})$ . If

$$\mathcal{H}_{K_p} = \{f_p : K_p \backslash G(\mathbb{Q}_p)/K_p \rightarrow \mathbb{Q}\} \tag{4.1}$$

is the local Hecke algebra, we obtain a map of  $\mathbb{Q}$ -algebras  $\mathcal{H}_{K_p} \rightarrow \mathcal{H}_K$  taking  $f_p$  to the function  $f = f_p \otimes \text{char}(\prod_{l \neq p} K_l)$  on  $G(\hat{\mathbb{Q}})$ . In fact, we obtain an isomorphism of the restricted tensor product of local algebras (with respect to the unit element) and  $\mathcal{H}_K$

$$\hat{\otimes}_p \mathcal{H}_{K_p} \cong \mathcal{H}_K. \tag{4.2}$$

We say the prime  $p$  is unramified for  $K$  if  $G(\mathbb{Q}_p)$  is split and  $K \cap G(\mathbb{Q}_p) = K_p$  is a hyperspecial maximal compact subgroup. In this case, the Satake isomorphism gives an identification [Ct; pg. 148]

$$\mathcal{H}_{K_p} \otimes_{\mathbb{Q}} \mathbb{Q}[p^{1/2}] \cong R(\hat{G}) \otimes_{\mathbb{Z}} \mathbb{Q}[p^{1/2}], \tag{4.3}$$

where  $\hat{G}$  is the dual Langlands group and  $R(\hat{G})$  its representation ring. The half-integral powers enter only in terms  $p^{\langle \lambda, \rho \rangle}$ , where  $\lambda$  is a co-character of a maximal torus  $T \subset G \otimes \mathbb{Q}_p$ , and  $\rho$  is half the sum of the positive roots relative to a Borel subgroup containing  $T$ . Since we have assumed that  $G$  is simply connected,  $\langle \lambda, \rho \rangle$  is always an integer, and the Satake transform gives an isomorphism of  $\mathbb{Q}$ -algebras

$$\mathcal{H}_{K_p} \cong R(\hat{G}) \otimes \mathbb{Q}. \tag{4.4}$$

Let  $\mathbb{T}$  be the commutative  $\mathbb{Q}$ -subalgebra of  $\mathcal{H}_K$  generated by the local algebras  $\mathcal{H}_{K_p}$  for all unramified  $p$ . Then by (4.4)

$$\mathbb{T} \cong \hat{\otimes}_{p \text{ unram}} R(\hat{G}) \otimes \mathbb{Q}. \tag{4.5}$$

**PROPOSITION 4.6.** *The elements of  $\mathbb{T}$  give commuting self-adjoint operators on  $A$ .*

*Proof.* We have

$$K t_p K = K t_p^{-1} K,$$

for all  $t_p$  in  $G(\mathbb{Q}_p)$ . Indeed, if  $T$  is a split torus in  $G(\mathbb{Q}_p)$ , then  $G(\mathbb{Q}_p) = K_p T K_p$ , by the Cartan decomposition. Since  $-1$  is in the Weyl group of  $G$ , there is an element  $n$  in  $K_l$  such that  $nt_p n^{-1} = t_p^{-1}$ . The proposition now follows from Proposition 3.4.

Let  $F$  be an eigenvector for  $\mathbb{T}$  acting on the space  $A \otimes \mathbb{C}$ . By (4.4),  $F$  gives rise to an element

$$s_p \in \text{Hom}(R(\hat{G}), \mathbb{C}), \quad (4.7)$$

for all unramified primes  $p$ . But the spectrum of  $R(\hat{G}) \otimes \mathbb{C}$  consists of the set of semi-simple conjugacy classes in  $\hat{G}(\mathbb{C})$ . Thus we have shown

**PROPOSITION 4.8.** *If  $F$  is an eigenvector for  $\mathbb{T}$  in  $A \otimes \mathbb{C}$ , the eigenvalues determine a collection  $\{s_p\}$  of semi-simple conjugacy classes in  $\hat{G}(\mathbb{C})$ , indexed by the unramified primes  $p$  for  $K$ .*

We note that by Proposition 4.6 each such eigenvector in  $A \otimes \mathbb{C}$  is actually defined over a totally real number field.

### 5. The Steinberg subspace

Assume that  $G$  is split and quasi-simple over  $\mathbb{Q}_p$ , and  $K_p$  a hyperspecial maximal compact subgroup of  $G(\mathbb{Q}_p)$ . We now consider the space  $A = A(K, W)$  of forms of weight  $W$  and level  $K$  in the special case when  $K = I_p \times K'$  where  $I_p$  is an Iwahori subgroup of  $G(\mathbb{Q}_p)$  contained in  $K_p$ . The Iwahori Hecke algebra  $\mathcal{H}_{I_p} = \mathcal{H}(G(\mathbb{Q}_p) // I_p)$  then has a distinguished rational character, corresponding to the Steinberg representation  $St_p$  of  $G(\mathbb{Q}_p)$ . This character sends the standard Iwahori-Matsumoto generators [Lu] of  $\mathcal{H}_{I_p}$  to  $-1$ .

Let

$$A(St_p) \subseteq A \quad (5.1)$$

be the  $\mathbb{Q}$ -subspace of modular forms on which  $\mathcal{H}_{I_p}$  acts by the Steinberg character. This is an  $\mathcal{H}_{K'}$ -submodule of  $A$ . Our aim in this section is to show it is a reasonably large subspace of  $A$ , so that there are many automorphic representations with local component  $St_p$ . To first order, we will show that:

$$\frac{\dim A(St_p)}{\dim A} = 1 - \frac{r+1}{p} + O\left(\frac{1}{p^2}\right), \quad r = \text{rank}(G). \quad (5.2)$$

The algebra  $\mathcal{H}_{I_p}$  contains the finite sub-algebra  $\mathcal{H}(K_p // I_p)$ . Let  $\epsilon_p$  be the restriction to  $\mathcal{H}(K_p // I_p)$  of the Steinberg character of  $\mathcal{H}_{I_p}$ . This character corresponds to the Steinberg representation of the finite Chevalley group  $G(p)$  [Ca]. The space  $A(St_p)$  is contained in the subspace

$$A(\epsilon_p) \subseteq A \quad (5.3)$$

on which the finite algebra acts by the character  $\varepsilon_p$ . To first order, we will show that

$$\frac{\dim A(\varepsilon_p)}{\dim A} = 1 - \frac{r}{p} + O\left(\frac{1}{p^2}\right), \quad r = \text{rank}(G). \tag{5.4}$$

Let  $\mathcal{F}$  be a maximal simplex in the building of  $G$  over  $\mathbb{Q}_p$ , which is fixed by the Iwahori subgroup  $I_p$ , and for each non-empty face  $\mathcal{F}_i$  of  $\mathcal{F}$  let  $I_p(i) \supseteq I_p$  be the stabilizer of  $\mathcal{F}_i$ . Let  $A(i)$  be the subspace of  $A$  of forms of weight  $W$  and level  $K(i) = I_p(i) \times K'$ .

Finally, we let  $A(1)$  be the subspace of  $A$  corresponding to the trivial 1-dimensional representation of  $G$ . Then  $\dim A(1) = 1$  when  $W = \mathbb{Q}$ , and  $\dim A(1) = 0$  otherwise.

**PROPOSITION 5.5.** *In the Grothendieck group of finite-dimensional  $\mathcal{H}_{K'}$ -modules*

$$A(\text{St}_p) + (-1)^r A(1) = \sum_{\mathcal{F}_i} (-1)^{\text{codim } \mathcal{F}_i} A(i)$$

$$A(\varepsilon_p) = \sum_{\mathcal{F}_i \supseteq \mathcal{F}_0} (-1)^{\text{codim } \mathcal{F}_i} A(i),$$

where  $\mathcal{F}_0$  is the hyperspecial vertex fixed by  $K_p$ .

*Proof.* The first follows from the Kottwitz’s formula [Ko]

$$\sum_{\mathcal{F}_i} (-1)^{\text{codim } \mathcal{F}_i} \dim(\pi^{I_p(i)}) = \begin{cases} 1 & \pi = \text{St}_p, \\ (-1)^r & \pi = 1, \\ 0 & \text{otherwise,} \end{cases}$$

for the Euler characteristic of the continuous cohomology of a unitary irreducible representation  $\pi$  of  $G(\mathbb{Q}_p)$ . The second formula follows from the standard resolution of the Steinberg character of the finite Chevalley group  $G(p)$  [Ca; pg. 187]. Note: if we include the empty face  $\mathcal{F}_\emptyset$ , with the stabilizer  $K(\emptyset) = G$ , then the formula for  $A(\text{St}_p)$  can be written without the correction term  $A(1)$ .

We can compute  $\dim A(i)$  if  $G(\mathbb{Q})$  acts freely on  $G(\hat{\mathbb{Q}})/I_p(i) \times K'$ . In this case

$$\dim A = (I_p(i) : I_p) \dim A(i). \tag{5.6}$$

We say that  $K'$  is  $p$ -neat if  $G(\mathbb{Q})$  acts freely on  $G(\hat{\mathbb{Q}})/I_p(i) \times K'$  for all  $i$ , and that it is weakly neat if  $G(\mathbb{Q})$  acts freely on  $G(\hat{\mathbb{Q}})/I_p(i) \times K'$  for all  $I_p(i) \subseteq I_p(0) = K_p$ . Proposition and (5.6) give a formula for  $\dim A(\text{St}_p)$  and  $\dim A(\varepsilon_p)$ :

**COROLLARY 5.7.** *If  $K'$  is weakly neat, we have*

$$\dim A = \prod_{i=1}^r \frac{p^{e_i+1} - 1}{p - 1} \dim A(0)$$

and

$$\dim A(\varepsilon_p) = \prod_{i=1}^r p^{e_i} \dim A(0).$$

If  $K'$  is neat we also have

$$\dim A(St_p) = \prod_{i=1}^r (p^{e_i} - 1) \dim A(0) - (-1)^r \dim A(1).$$

Here  $e_1, e_2, \dots, e_r$  are the exponents for the Weyl group of  $G$  [Bu; pg. 118].

*Proof.* This is standard inclusion-exclusion [Se1; pgs 664–667]. For example

$$\prod_{i=1}^r \frac{p^{e_i+1} - 1}{p - 1} = (K_p : I_p) = (G(p) : B(p))$$

$$\prod_{i=1}^r p^{e_i} = p^{\dim U(p)} = \sum_{I_p(i) \subseteq K_p} (-1)^{\text{codim } \mathcal{F}_i} (K_p : I_p(i)),$$

where  $B(p)$  is a Borel subgroup of  $G(p)$  and  $U(p)$  the unipotent radical of  $B(p)$ .

### 6. The case $G = \text{Aut}(\mathbb{O})$

We work out some details of the theory presented in this chapter for the simplest case of a group  $G$  with a model over  $\mathbb{Z}$  with  $G(\mathbb{R})$  compact, and  $G(\mathbb{Q}_p)$  split for all  $p$ . Namely  $G$  is the simple group of type  $G_2$  over  $\mathbb{Q}$  defined as the automorphism group of Cayley's octonion algebra  $\mathbb{O}$  [J3]. We recall that  $\mathbb{O}$  is a non-associative division algebra of rank 8 over  $\mathbb{Q}$

$$\begin{cases} \mathbb{Q} + \mathbb{Q}e_1 + \mathbb{Q}e_2 + \mathbb{Q}e_3 + \mathbb{Q}e_4 + \mathbb{Q}e_5 + \mathbb{Q}e_6 + \mathbb{Q}e_7, \\ e_i^2 = -1 \quad \text{all } i, \\ e_i \cdot (e_{i+1} \cdot e_{i+3}) = (e_i \cdot e_{i+1}) \cdot e_{i+3} \quad \text{all } i \pmod{7}. \end{cases} \quad (6.1)$$

The map  $x = a_0 + \sum a_i e_i \mapsto \bar{x} = a_0 - \sum a_i e_i$  defines an anti-involution of  $\mathbb{O}$ , with fixed field  $\mathbb{Q}$ .

On  $\mathbb{O}$ , we have the trace

$$\begin{aligned} \text{Tr}: \mathbb{O} &\rightarrow \mathbb{Q} \\ x &\mapsto x + \bar{x} = 2a_0, \end{aligned} \quad (6.2)$$

which is  $\mathbb{Q}$ -linear, and the norm

$$\text{N}: \mathbb{O} \rightarrow \mathbb{Q},$$

$$x \mapsto x \cdot \bar{x} = \bar{x} \cdot x = a_0^2 + \sum a_i^2 \tag{6.3}$$

which satisfies  $\mathbb{N}(x \cdot y) = \mathbb{N}(x)\mathbb{N}(y)$ . Although the multiplication is neither commutative nor associative, we have

$$\begin{aligned} \text{Tr}(x \cdot y) &= \text{Tr}(y \cdot x) \\ \text{Tr}(x \cdot (y \cdot z)) &= \text{Tr}((x \cdot y) \cdot z). \end{aligned} \tag{6.4}$$

We denote the latter rational number simply by  $\text{Tr}(xyz)$ .

Let  $\mathcal{R}$  (see [Co]) be the  $\mathbb{Z}$ -lattice in  $\mathbb{O}$  spanned by the  $e_i$  and the elements

$$\begin{cases} \frac{1}{2}(1 + e_1 + e_2 + e_4), \\ \frac{1}{2}(1 + e_1 + e_3 + e_7), \\ \frac{1}{2}(1 + e_1 + e_5 + e_6), \\ \frac{1}{2}(e_1 + e_2 + e_3 + e_5). \end{cases} \tag{6.5}$$

Then  $\mathcal{R}$  is stable under octonionic multiplication, and  $G = \text{Aut}(\mathcal{R})$  is the unique model over  $\mathbb{Z}$  with good reduction at all primes [Gr]. We write  $G(p)$  for the finite group  $G(\mathbb{F}_p) = \text{Aut}(\mathcal{R}/p\mathcal{R})$ .

The groups  $\Gamma_\alpha$  stabilizing the cosets  $g_\alpha K$  (2.2) have orders dividing  $2^6 3^3 7$  [Se2]. When  $K \subseteq G(\hat{\mathbb{Z}})$  they are all subgroups of  $G(\mathbb{Z})$ . The group  $G(\mathbb{Z})$  has order  $2^6 3^3 7 = 12096$ , and is isomorphic to  $G(2)$  under reduction modulo 2 [A].

The irreducible representations  $W$  of  $G$  considered in Section 1 of this chapter, can all be constructed from the irreducible representation  $V$  on octonions with trace 0. Namely, the 14-dimensional adjoint representation  $\mathfrak{g}$  of  $G$  is the kernel of the map

$$\begin{aligned} \wedge^2 V &\rightarrow V, \\ v \wedge w &\mapsto v \cdot w - w \cdot v \end{aligned} \tag{6.6}$$

and for  $k_1, k_2 \geq 0$  there is an irreducible representation  $W = W(k_1, k_2)$  of  $G$  defined over  $\mathbb{Q}$  which occurs as the  $G$ -submodule of highest weight in  $V^{\otimes k_1} \otimes \mathfrak{g}^{\otimes k_2}$ .  $W$  has dimension

$$\frac{(k_1 + 1)(k_2 + 1)(k_1 + k_2 + 2)(k_1 + 2k_2 + 3)(k_1 + 3k_2 + 4)(2k_1 + 3k_2 + 5)}{120}. \tag{6.7}$$

We fix the inner product  $\langle , \rangle$  on  $W$  by taking  $\langle v, w \rangle = \text{Tr}(\bar{v}w)$  on  $V$ , using the second exterior power of this product on  $\mathfrak{g} \subset \wedge^2 V$ , and then taking the tensor product of the previously defined inner products on  $W \subseteq V^{\otimes k_1} \otimes \mathfrak{g}^{\otimes k_2}$ .

Let  $K_p = G(\mathbb{Z}_p)$ . We make the Satake isomorphism (4.4)

$$\mathcal{H}_{K_p} \cong R(\hat{G}) \otimes \mathbb{Q},$$

completely explicit. Let  $T \subset B \subset G$  be a maximal split torus in a Borel subgroup, all defined over  $\mathbb{Z}_p$ . Let  $\{\alpha_1, \alpha_2\}$  be the corresponding root basis for the character group of  $T$ , where  $\alpha_1$  long and  $\alpha_2$  short, and let  $\check{\omega}_1$  and  $\check{\omega}_2$  be the dual basis for the co-characters. We define

$$\begin{cases} t_1 = \text{char}(K_p \check{\omega}_1(p) K_p), \\ t_2 = \text{char}(K_p \check{\omega}_2(p) K_p) \end{cases} \tag{6.8}$$

in  $\mathcal{H}_{K_p}$ . These have degrees (the number of single  $K_p$ -cosets)

$$\begin{cases} d(t_1) = p \frac{p^6-1}{p-1}, \\ d(t_2) = p^5 \frac{p^6-1}{p-1}. \end{cases} \tag{6.9}$$

The elements  $\check{\omega}_1$  and  $\check{\omega}_2$  are the fundamental weights of the dual group  $\hat{G}(\mathbb{C}) = G_2(\mathbb{C})$ . Since  $\check{\omega}_1$  is short and  $\check{\omega}_2$  is long,  $\check{\omega}_1$  corresponds to the 7-dimensional representation  $\hat{V}$  and  $\check{\omega}_2$  corresponds to the 14-dimensional adjoint representation  $\hat{\mathfrak{g}}$ . Let  $\chi_1$  and  $\chi_2$  denote the characters of these representations, so  $R(\hat{G}) = \mathbb{Z}[\chi_1, \chi_2]$ .

In the inverse of the Satake isomorphism

$$\begin{cases} \chi_1 \text{ maps to } (t_1 + 1)/p^3, \\ \chi_2 \text{ maps to } (t_2 + t_1 + p^4 + 1)/p^5, \end{cases} \tag{6.10}$$

Hence  $\mathcal{H}_{K_p} = \mathbb{Q}[t_1, t_2]$ . If  $F$  in  $A \otimes \mathbb{R}$  is an eigenvector for  $\mathcal{H}_{K_p}$  with

$$\begin{cases} t_1|F = \lambda_1 F, \\ t_2|F = \lambda_2 F, \end{cases} \tag{6.11}$$

then the semi-simple class  $s = s_p(F)$  in  $\hat{G}(\mathbb{C})$  has the following characteristic polynomial on  $\hat{V}$

$$\det(1 - sT|\hat{V}) = 1 - a_1T + a_2T^2 - a_3T^3 + a_4T^4 - a_5T^5 + a_6T^6 - T^7, \tag{6.12}$$

where

$$\begin{aligned} a_1 &= (\lambda_1 + 1)/p^3, \\ a_2 &= (\lambda_2 + (p^2 + 1)\lambda_1 + (p^4 + p^2 + 1))/p^5, \end{aligned}$$

$$a_3 = a_1^2 + a_1 - a_2$$

and  $a_i = a_{7-i}$  for  $i = 1, \dots, 6$ .

The Iwahori Hecke algebra  $\mathcal{H}_{I_p}$  has generators  $T_0, T_1, T_2$  and relations

$$\begin{aligned} (T_i - p)(T_i + 1) &= 0, & i = 0, 1, 2, \\ T_0T_2 &= T_2T_0, \\ T_0T_1T_0 &= T_1T_0T_1, \\ (T_1T_2)^3 &= (T_2T_1)^3. \end{aligned} \tag{6.13}$$

The subalgebra  $\mathcal{H}(K_p//I_p) \cong \mathcal{H}(G(p)//B(p))$  has generators  $T_1$  and  $T_2$ .

7. *Examples of modular forms on  $G = \text{Aut}(\mathbb{O})$*

We now do some explicit examples, where  $K$  is a subgroup of finite index in  $G(\hat{\mathbb{Z}})$ . Let  $p$  be a rational prime, and let  $B(p) \subset G(p)$  be a Borel subgroup. We let

$$K(p) \subseteq K_0(p) \subseteq G(\hat{\mathbb{Z}}) \tag{7.1}$$

be the subgroups reducing to 1 (mod  $p$ ) and to  $B(p)$  (mod  $p$ ) respectively. Then  $K(p)$  is a normal subgroup of  $G(\hat{\mathbb{Z}})$ , and the local component of  $K_0(p)$  at  $p$  is an Iwahori subgroup. In particular, the spaces

$$A(\text{St}_p) \subseteq A(\varepsilon_p) \subseteq A(W, K_0(p)) \tag{7.2}$$

are defined.

Consider first the case when  $K = K(2)$  and  $W$  is arbitrary. Since  $G(\hat{\mathbb{Q}}) = G(\mathbb{Q})G(\hat{\mathbb{Z}})$ , and  $G(\mathbb{Z}) = G(2) [\text{Gr}]$ ,

$$G(\hat{\mathbb{Q}}) = G(\mathbb{Q}) \times K(2), \tag{7.3}$$

so we have one double coset, with  $\Gamma = 1$ . Hence by (2.3)

$$A(W, K(2)) \cong W \tag{7.4}$$

as  $\mathbb{Q}$ -vector spaces. This is actually an isomorphism of  $G(2) = G(\mathbb{Z})$ -modules. By (2.3) we obtain isomorphisms

$$\begin{cases} A(W, K_0(2)) \cong W^{B(2)}, \\ A(W, G(\hat{\mathbb{Z}})) \cong W^{G(2)} \end{cases} \tag{7.5}$$

of  $\mathbb{Q}$ -vector spaces. The former is an isomorphism of  $\mathcal{H}(G(\hat{\mathbb{Z}})//K_0(2)) \cong \mathcal{H}(G(2)//B(2))$ -modules.

Consider the special case when  $W = W(1, 1)$  has dimension  $64 = 2^6$ . The restriction of  $W$  to  $G(\hat{\mathbb{Z}})$  is isomorphic to the Steinberg representation  $st_2$  of  $G(2)$ . Hence

$$A(\varepsilon_2) = A(W, K_0(2)) \tag{7.6}$$

is one-dimensional.

**PROPOSITION 7.7.** *There exists a unique automorphic representation  $\pi$  of  $G(\mathbb{A})$  with  $\pi_\infty \cong W(1, 1) \otimes \mathbb{C}$ ,  $\pi_2 \cong St_2$ , the Steinberg representation, and  $\pi_p$  unramified for all  $p \neq 2$ .*

*Proof.* The  $K_0(2)$ -fixed vectors in such a  $\pi$  contribute a line to the space  $A(St_2) \otimes \mathbb{C}$ , so we must show that  $A(\varepsilon_2) = A(St_2)$ .

The elements  $T_1$  and  $T_2$  generate the Hecke algebra  $\mathcal{H}(G(2)//B(2))$ . Since  $T_1 = T_2 = -1$  on  $A(\varepsilon_2)$ , and  $T_0T_1T_0 = T_1T_0T_1$ , we have  $-T_0^2 = T_0$  on  $A(\varepsilon_2)$ , so  $T_0$  must act as  $-1$  also.

Finally, consider the case when  $W = W(0, 0) = \mathbb{Q}$  is the trivial representation of  $G$  and  $K = K_0(p)$ . From (7.2) we have an isomorphism of  $\mathbb{Q}$ -vector spaces

$$\begin{cases} A(\mathbb{Q}, K_0(p)) \cong (\text{Ind}_{B(p)}^{G(p)} \mathbb{Q})^{G(\mathbb{Z})}, \\ A(\mathbb{Q}, K_0(p))(\varepsilon_p) \cong (st_p)^{G(\mathbb{Z})}. \end{cases} \tag{7.8}$$

Here  $st_p$  is the Steinberg representation of  $G(p)$ . Its dimension is  $p^6$ , and appears with multiplicity one in the induced representation from  $B(p)$ .

Let  $d(p) = \dim(st_p)^{G(\mathbb{Z})}$ . For small primes  $p$ , we have the following table (computed by D. Pollack and J. Lansky):

$p$	2	3	5	7	11	13	17	19	
$d(p)$	0	0	1	13	142	416	1980	3931.	(7.9)

For  $p \neq 2, 3, 7$ , K. Magaard has shown that

$$d(p) = (p^6 \pm 56p^3 + 315p^2 + ap + b)/12096, \tag{7.10}$$

where the sign  $\pm$  is chosen so that  $p \equiv \pm 1 \pmod{3}$ , and the coefficients  $a$  and  $b$  depend on the congruence of  $p$  modulo 24:

$p \equiv$	1(24)	5(24)	7(24)	11(24)	13(24)	17(24)	19(24)	23(24)	
$a$	1932	-420	420	-1932	1932	-420	420	-1932	(7.11)
$b$	9792	-2304	3744	3744	3744	3744	-2304	9792	

**PROPOSITION 7.12.** *There is a unique automorphic representation  $\pi$  of  $G(\mathbb{A})$  with  $\pi_\infty \cong \mathbb{C}$ ,  $\pi_5 \cong \text{St}_5$ , and  $\pi_p$  unramified for  $p \neq 5$ .*

*Proof.* We must show that

$$A(\mathbb{Q}, K_0(5))(\text{St}_5)$$

is one-dimensional. To do this, we will compute the dimensions of the spaces  $A(\mathbb{Q}, K(i))$ , where  $K(i) = \prod_{p \neq 5} G(\mathbb{Z}_p) \times I_5(i)$  and  $I_5(i)$  is an arbitrary parahoric at the prime 5. The parahorics are indexed by the facets of a 30-60-90 triangle (a maximal simplex in the building, the white vertex is hyperspecial), and we will find the dimensions

This gives  $\dim A(\text{St}_5) = 7 - (3 + 3 + 4) + (1 + 1 + 3) - 1 = 1$  by Kottwitz's formula (5.5). The dimensions

are easily computed by the above considerations, as the corresponding parahorics  $I_5(i)$  are contained in  $G(\mathbb{Z}_5)$ . Now let  $I_5(i)$  be the maximal parahoric whose reduction (mod 5) is  $\text{SL}_3(5)$ . Using the mass formula [Gr], we find

$$\sum_{G(\mathbb{Q}) \backslash G(\hat{\mathbb{Q}}) / K(i)} \frac{1}{\#\Gamma_\alpha} = \frac{1}{2^5 3}.$$

Since every finite subgroup of  $K(i)$  has order dividing  $2^5 3$ , we find a single double coset, with stabilizer of order  $2^5 3$ , reducing to the normalizer of a maximal split torus in  $\text{SL}_3(5)$ . Hence  $\dim A(\mathbb{Q}, K(i)) = 1$ , so we have obtained the dimensions:

Since the normalizer of a split maximal torus in  $SL_3(5)$  has precisely 3 orbits on  $\mathbb{P}^2(5)$ , we obtain the dimensions:

It remains to compute the dimension for  $K(i)$  with local component  $I_5(i)$  maximal, whose reduction (mod 5) is split  $SO_4(5)$ . Here the mass formula yields

$$\sum_{G(\mathbb{Q}) \backslash G(\hat{\mathbb{Q}}) / K(i)} \frac{1}{\#\Gamma_\alpha} = \frac{31}{2^6 3^2}.$$

Hence the number of double cosets is either 2 or 3. Since the order of a finite subgroup of  $K(i)$  divides  $2^6 3^2$ , and we cannot write the mass as a sum of two such terms, the dimension is 3 as claimed.

## 2. Motives

In this chapter, we present a conjecture on motives of rank 7 over  $\mathbb{Q}$  associated to automorphic forms on the anisotropic form  $G = \text{Aut}(\mathbb{O})$  of  $G_2$ . Since we hope to construct these motives as the orthogonal complement of a Hodge class in a motive of rank 8, we give local criteria which allow one to show that a subgroup  $\Gamma$  of  $SO_8$  is contained in either  $\text{Spin}_7$  or  $G_2 = \text{Spin}_7 \cap SO_7$ . Finally, we discuss the simply connected form of  $E_7$  of rank 3 over  $\mathbb{Q}$ , its 56-dimensional representation, and the dual pair  $G \times G' = \text{Aut}(\mathbb{O}) \times PGS p_6$  in the associated adjoint group.

### 1. A conjecture on $G_2$ -motives

Let  $G = \text{Aut}(\mathcal{R})$  be the form of  $G$  over  $\mathbb{Z}$  constructed in (6.2) in Chapter I, and fix a finite, non-empty set  $S$  of primes. For  $p$  in  $S$ , let  $K_p \subset G(\mathbb{Z}_p)$  be an Iwahori subgroup. For  $p$  not in  $S$ , let  $K_p = G(\mathbb{Z}_p)$ .

Fix an irreducible representation  $W$  of  $G$ , and put  $K = \prod_p K_p$ . Let  $A = A(W, K)$  be the associated space of automorphic forms, and

$$A_S = A(St_S) \subseteq A, \quad (1.1)$$

the subspace which is localized at the Steinberg representation  $St_p$ , for all primes  $p$  in  $S$ . Then  $A_S$  is a finite-dimensional inner product space over  $\mathbb{Q}$ , with

$$\dim A_S \approx \frac{\dim W}{12096} \prod_{p \in S} (p^5 - 1)(p - 1), \quad (1.2)$$

by (5.2) of Section 1.

The spherical Hecke algebra  $\hat{\otimes}_{p \notin S} \mathcal{H}(G(\mathbb{Q}_p) // G(\mathbb{Z}_p))$  acts on  $A_S$ , via self-adjoint commuting operators. Let  $F$  be a simultaneous eigenvector, defined over a totally real number-field  $E$ . Then  $F$  corresponds to an irreducible automorphic representation of  $G(\mathbb{A})$

$$\pi = \hat{\otimes} \pi_v, \tag{1.3}$$

with  $\pi_\infty \cong W \otimes \mathbb{C}$ ,  $\pi_p \cong St_p$  for all  $p$  in  $S$  and  $\pi_p$  spherical for all primes  $p$  not in  $S$ .

**CONJECTURE 1.4.** *Associated to the eigenvector  $F$  in  $A_S$  (or to the automorphic representation  $\pi$ ), there is a motive  $M$  of rank 7 and weight 0 over  $\mathbb{Q}$  with coefficients in  $E$ . The motive  $M$  enjoys the following local properties.*

- (1) *Assume  $W = W(k_1, k_2)$ . The Hodge components  $M^{p,q}$  of  $M_B \otimes \mathbb{C}$  have rank 1 over  $E \otimes \mathbb{C}$  for those  $(p, q)$  which satisfy  $p + q = 0$  and*

$$\begin{aligned} p &= 3 + k_1 + 2k_2 \\ &2 + k_1 + k_2 \\ &1 + k_2 \\ &0 \\ &-(1 + k_2) \\ &-(2 + k_1 + k_2) \\ &-(3 + k_1 + 2k_2). \end{aligned}$$

*Otherwise  $M^{p,q} = 0$ . The real Frobenius  $F_\infty$  acts as  $-1$  on  $M^{0,0}$ .*

- (2) *Assume  $p \notin S$ , so  $\pi_p$  is spherical with Satake parameter  $s_p$ . Let  $\lambda$  be a finite prime of  $E$  not dividing  $p$ . Then the  $\lambda$ -adic representation  $M_\lambda$  of  $\text{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$  is unramified at  $p$ . If  $F_p$  is a Frobenius element, then*

$$\det(1 - F_p T | M_\lambda) = \det(1 - s_p T | \hat{V}_\mathbb{C})$$

*has coefficients in  $E$ .*

- (3) *Assume  $p \in S$ , so  $\pi_p \cong St_p$ . Let  $\lambda$  be a finite prime of  $E$  not dividing  $p$ . Then the  $\lambda$ -adic representation  $M_\lambda$  of  $\text{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$  is tamely ramified at  $p$ , and isomorphic to  $\text{Sym}^6 H^1(X, E_\lambda)(3)$ , where  $X$  is a Tate elliptic curve over  $\mathbb{Q}_p$ .*

In particular, part (2) of the conjecture implies that the local components of  $\pi$  are all tempered. This need not be true for arbitrary eigenvectors  $F$  in  $A \otimes \mathbb{C}$ , but should be true for eigenvectors in the subspace  $A(St_p)$  for any  $p$  in  $S$ . Also, we expect the spectrum of the spherical Hecke algebra to be multiplicity free on  $A_S \otimes \mathbb{R}$ .

If the motive of Conjecture 1.4 exists, its  $L$ -function at finite primes is given by the Euler product

$$L(M, s) = \prod_{p \in S} (1 - p^{-3-s})^{-1} \prod_{p \notin S} \det(1 - s_p \cdot p^{-s} | \hat{V})^{-1}, \tag{1.6}$$

which converges for  $\text{Re}(s) > 1$ . This is a Dirichlet series  $\sum_{n \geq 1} a_n n^{-s}$  with coefficients in the subfield  $E$  of  $\mathbb{C}$ . If (see [De], pg. 329)

$$L_\infty(M, s) = \Gamma_{\mathbb{C}}(s + (3 + k_1 + 2k_2)) \times \Gamma_{\mathbb{C}}(s + (2 + k_1 + k_2)) \Gamma_{\mathbb{C}}(s + (1 + k_2)) \Gamma_{\mathbb{R}}(s + 1) \tag{1.7}$$

is the Archimedean  $L$ -factor, then the product  $\Lambda(M, s) = L_\infty(M, s)L(M, s)$  should have an analytic continuation to the entire  $s$ -plane, and satisfy the functional equation

$$\Lambda(M, s) = N^{\frac{1}{2}-s} \Lambda(M, 1 - s),$$

with exponential factor  $N = \prod_{p \in S} p^6$ .

The fact that  $F_\infty = -1$  on  $M^{0,0}$  implies that  $s = 0$  and  $s = 1$  are critical for  $L(M, s)$ , in the sense of Deligne [De; pg. 318]. If  $M$  is realized as the complement of a Hodge class in the orthogonal motive  $M'$  of rank 8, as suggested in the introduction, then

$$\begin{cases} L(M', s) = \zeta(s)L(M, s), \\ L(M, 1) = \text{Res}_{s=1} L(M', s) ds. \end{cases} \tag{1.8}$$

2. Subgroups of  $O_8$

As described in the introduction, we hope to construct  $M \subset M' \subseteq H_c^6(X, \mathcal{F})$  (3), where  $M'$  is an orthogonal motive of rank 8. It is therefore useful to have criteria which allow to conclude that the motivic Galois group of  $M'$  is a proper subgroup of the orthogonal group  $O(M') = O_8$ .

Let  $W$  be a non-degenerate quadratic space of dimension 8 over  $\mathbb{C}$ , and let  $s$  be a semi-simple conjugacy class in  $O(W) = O_8$ . Let

$$f(T) = \det(1 - sT | W) = \sum_{k=0}^8 (-1)^k \text{Tr}(s | \wedge^k W) T^k \tag{2.1}$$

be the characteristic polynomial of  $s$  on  $W$ .

PROPOSITION 2.2.

(1) *If  $s$  lives in the normal subgroup  $SO_8$  of elements with  $\det(s) = 1$ , then  $f(T)$  has the form*

$$f(T) = 1 - AT + BT^2 - CT^3 + DT^4 - CT^5 + BT^6 - AT^7 + T^8,$$

where the coefficients  $(A, B, C, D)$  are (arbitrary) elements in  $\mathbb{C}^4$ .

(2) If  $s$  lies in the subgroup  $\mathrm{SO}_7 \subset \mathrm{SO}_8$  fixing a non-isotropic line, or in the subgroup  $\mathrm{SO}_3 \times \mathrm{SO}_5 \subset \mathrm{SO}_8$  stabilizing an orthogonal decomposition  $W = W_3 \oplus W_5$ , then the coefficients  $(A, B, C, D)$  of  $f(T)$  are (arbitrary) elements in the hyperplane

$$2A - 2B + 2C - D - 2 = 0.$$

(3) If  $s$  lies in the subgroup  $\mathrm{Spin}_7 \subset \mathrm{SO}_8$  embedded by the spin representation, or in the subgroup  $\mathrm{SL}_2 \times \mathrm{Sp}_4 / \Delta \langle \pm 1 \rangle \cong \mathrm{Spin}_3 \times \mathrm{Spin}_5 / \Delta \langle \pm 1 \rangle \subset \mathrm{SO}_8$  embedded by the tensor product of the two spin representations, then the coefficients  $(A, B, C, D)$  of  $f(T)$  are (arbitrary) elements in the hypersurface

$$A^2(D + 2B + 1) = C^2 + 2AC + A^4.$$

(4) If  $s$  lies in the subgroup  $G_2 = \mathrm{Spin}_7 \cap \mathrm{SO}_7 \subset \mathrm{SO}_8$  of  $\mathrm{Spin}_7$  fixing a non-isotropic line, or in the subgroup  $\mathrm{PGL}_3 \subset \mathrm{SO}_8$  embedded by the adjoint representation, then the coefficients  $A$  and  $B$  of  $f(T)$  are (arbitrary) elements of  $\mathbb{C}$ , and the coefficients  $C$  and  $D$  are given by

$$\begin{cases} C = A^2 - A, \\ D = 2(A^2 - B - 1). \end{cases}$$

*Proof.* (1) This is well-known. (2) If  $s$  lies in  $\mathrm{SO}_7$ , then  $f(T) = (T - 1)g(T)$ , so  $f(1) = 1$ . This gives the linear relation on coefficients. In fact,  $g(T) = (T - 1)h(T)$ , although this gives no new relations. The same holds for  $s$  in  $\mathrm{SO}_3 \times \mathrm{SO}_5$ , as  $s = s_1 \times s_2$ , where  $s_1$  fixes a vector in the 3-dimensional representation  $W_3$ , and  $s_2$  fixes a vector in the 5-dimensional representation  $W_5$ .

(3) In these two cases, the smallest degree invariant lies in  $\wedge^4 W$ , where there is a unique fixed line. The polynomial relation is computed from the representation rings of the two groups.

(4) These equations are simply a combination of (2) and (3). They state that the roots of  $f(T)$  have the form  $\{1, 1, \alpha, \beta, \gamma, \alpha^{-1}, \beta^{-1}, \gamma^{-1}\}$  with  $\alpha\beta\gamma = 1$ . This is also true for semi-simple elements in  $\mathrm{PGL}_3$ .

We say that a subgroup  $\Gamma \subseteq \mathrm{SO}_8$  is locally contained in  $\mathrm{SO}_7$  if the coefficients of the characteristic polynomials of all elements  $s$  in  $\Gamma$  satisfy the equation in (2), Proposition 2.2. Similarly, we say that  $\Gamma \subseteq \mathrm{SO}_8$  is locally contained in  $\mathrm{Spin}_7$  if the coefficients of the characteristic polynomials of all elements  $s$  in  $\Gamma$  satisfy the equation in (3), Proposition 2.2. Note that the group  $\mathrm{SO}_3 \times \mathrm{SO}_5$  is locally contained in  $\mathrm{SO}_7$ , even though it does not globally fix a line. Similarly, the group  $\mathrm{Spin}_3 \times \mathrm{Spin}_5 / \Delta \langle \pm 1 \rangle$  is locally contained in  $\mathrm{Spin}_7$ . If we introduce regular unipotent elements, we can eliminate these examples.

**PROPOSITION 2.3.** *Let  $\Gamma \subseteq \mathrm{SO}_8$  be a subgroup which acts semi-simply on  $W$ . Assume that*

- (1)  $\Gamma$  contains a regular unipotent element  $u$ .
- (2)  $\Gamma$  is locally contained in  $\mathrm{SO}_7$ .

Then  $\Gamma$  is contained in  $\mathrm{SO}_7$ .

Similarly, assume that

- (1)  $\Gamma$  contains a regular unipotent element  $u$ .
- (2)  $\Gamma$  is locally contained in  $\mathrm{Spin}_7$ .

Then  $\Gamma$  is contained in  $\mathrm{Spin}_7$ .

*Proof.* We use the fact that the connected, reductive subgroups of  $\mathrm{SO}_8$  containing a regular unipotent  $u$  form a chain:

where  $G_2 = \mathrm{SO}_7 \cap \mathrm{Spin}_7$ , and  $\mathrm{PGL}_2$  is the principal subgroup of  $\mathrm{SO}_8$  determined by  $u$ .

Let  $C \subseteq \mathrm{SO}_8$  be the Zariski closure of  $\Gamma$ . Then the connected component  $C^0$  is reductive, as it has a faithful semi-simple representation  $W$ . It also contains a regular unipotent element, so is one of the groups in the chain. If  $\Gamma$  is locally contained in  $\mathrm{SO}_7$ , then so is  $C$ , hence

$$C^0 = \mathrm{SO}_7, \quad G_2 \quad \text{or} \quad \mathrm{PGL}_2.$$

The normalizers of these in  $\mathrm{SO}_8$  are  $C^0 \times \langle \pm 1 \rangle$ , but  $-1$  is not locally contained in  $\mathrm{SO}_7$ . Hence  $C$  is connected, and  $\Gamma$  is contained in  $\mathrm{SO}_7$ .

The same argument works when  $\Gamma$  is locally contained in  $\mathrm{Spin}_7$ , but now  $C$  can be  $G_2 \times \langle \pm 1 \rangle$  or  $\mathrm{PGL}_2 \times \langle \pm 1 \rangle$ . Since these are both contained in  $\mathrm{Spin}_7$ ,  $\Gamma$  is contained in  $\mathrm{Spin}_7$ .

**COROLLARY 2.4.** *Let  $\Gamma \subseteq \mathrm{SO}_8$  be a subgroup which acts semi-simply on  $W$ . Assume that*

- (1)  $\Gamma$  contains a regular unipotent element  $u$ .
- (2)  $\Gamma$  is locally contained in  $G_2$ : the coefficients of the characteristic polynomial of  $s \in \Gamma$  satisfy the equations in Proposition 2.2, part (4).

Then  $\Gamma$  is contained in  $G_2$ .

*Proof.* This is a combination of the two results of Proposition 2.3, as  $G_2 = \mathrm{Spin}_7 \cap \mathrm{SO}_7$  in  $\mathrm{SO}_8$ . The proof shows that the Zariski closure of  $\Gamma$  in  $O_8$  is either  $G_2$ , or the principal  $\mathrm{PGL}_2$  in  $G_2$  determined by  $u$ .

### 3. A form of $E_7$

As mentioned in the introduction, there is a (unique) form  $H$  of the split adjoint group of type  $E_7$ , which has rank 3 over  $\mathbb{Q}$ . This group is split over  $\mathbb{Q}_p$  for all primes  $p$ , and acts on the exceptional tube domain over  $\mathbb{R}$ ; it can be constructed from the Cayley division algebra  $\mathbb{O}$  [Fr]. We sketch such a construction of the simply connected double cover  $H_{sc}$  over  $\mathbb{Q}$ , which lies in the exact sequence of algebraic groups

$$1 \rightarrow \mu_2 \rightarrow H_{sc} \rightarrow H \rightarrow 1. \quad (3.1)$$

The construction is based on the existence of a faithful representation  $W$  of dimension 56 over  $\mathbb{Q}$ . We note that the only other simply-connected group of type  $E_7$  admitting a 56-dimensional representation over  $\mathbb{Q}$  is the split form.

Let  $J_{\mathbb{O}}$  be the exceptional 27-dimensional Jordan algebra of all  $3 \times 3$  Hermitian symmetric matrices over  $\mathbb{O}$

$$A = \begin{pmatrix} a & z & \bar{y} \\ \bar{z} & b & x \\ y & \bar{x} & c \end{pmatrix}, \quad (3.2)$$

where  $a, b, c$  lie in  $\mathbb{Q}$  and  $x, y, z$  lie in  $\mathbb{O}$ . The Jordan multiplication is given by the formula

$$A \circ B = \frac{1}{2}(AB + BA). \quad (3.3)$$

There is a cubic form  $\det: J_{\mathbb{O}} \rightarrow \mathbb{Q}$ , defined by

$$\det(A) = abc + \operatorname{Tr}(xyz) - a\mathbb{N}(x) - b\mathbb{N}(y) - c\mathbb{N}(z). \quad (3.4)$$

Let  $(A, B, C)$  be the unique symmetric trilinear form such that [EG]

$$(A, A, A) = 6 \det(A). \quad (3.5)$$

Let  $M$  be the reductive algebraic group over  $\mathbb{Q}$  of invertible linear mappings  $m: J_{\mathbb{O}} \rightarrow J_{\mathbb{O}}$  which satisfy

$$\det(m(A)) = \lambda(m)\det(A), \quad (3.6)$$

for a similitude  $\lambda(m)$  in  $\mathbb{Q}^\times$ . The center of  $M$  is  $\mathbb{G}_m$ , acting by scalar matrices, and the kernel of the morphism  $\lambda: M \rightarrow \mathbb{G}_m$  is a simply connected group of type  $E_6$  and rank 2 over  $\mathbb{Q}$  [CS]. On the center,  $\lambda(a) = a^3$ .

Let  $N$  be a unipotent Abelian group over  $\mathbb{Q}$ , isomorphic to  $J_{\mathbb{O}}$ . In  $H_{sc}$  we have a maximal parabolic subgroup

$$P_{sc} = MN, \quad (3.7)$$

where the conjugation action of  $M$  on  $N$  is given by

$$mA m^{-1} = \lambda^{-1}(m) m(A). \quad (3.8)$$

Note that this action has a kernel  $\mu_2$  (the center of  $H_{sc}$ ).

We now define a representation of  $P_{sc}$  on the 56-dimensional module

$$W = \mathbb{Q} \oplus J_{\mathbb{O}} \oplus J_{\mathbb{O}}^* \oplus \mathbb{Q}^*, \quad (3.9)$$

where  $J_{\mathbb{O}}^* = \text{Hom}(J_{\mathbb{O}}, \mathbb{Q})$ , and  $\mathbb{Q}^* = \text{Hom}(\mathbb{Q}, \mathbb{Q}) \cong \mathbb{Q}$ . The subgroup  $M$  acts on  $W$  by

$$m(y, Y, Y^*, y^*) = (\lambda(m)y, m(Y), m^*(Y^*), \lambda^{-1}(m)y^*), \quad (3.10)$$

where  $m^*$  is defined as follows; if  $\langle X, Y^* \rangle$  is the pairing  $J_{\mathbb{O}} \times J_{\mathbb{O}}^* \rightarrow \mathbb{Q}$ , we have  $\langle mX, m^*Y^* \rangle = \langle X, Y^* \rangle$  for all  $X \in J_{\mathbb{O}}$  and  $Y^* \in J_{\mathbb{O}}^*$ . One can give complicated formulas for the action of  $N$  on  $W$  [Ki; pg. 143], but since we are in characteristic 0, it suffices to define the action of  $\text{Lie}(N) \cong J_{\mathbb{O}}$ . This acts by

$$X(y, Y, Y^*, y^*) = (0, yX, X \times Y, \langle X, Y^* \rangle). \quad (3.11)$$

where  $X \times Y$  is the element of  $J_{\mathbb{O}}^*$  mapping  $Z$  to  $\langle X, Y, Z \rangle$ .

Using (3.8), one can check that the formulas (3.10) and (3.11) define an action of  $P_{sc}$  on  $W$ , which preserves the natural symplectic form

$$\begin{aligned} & \{(x, X, X^*, x^*), (y, Y, Y^*, y^*)\} \\ &= (xy^* - yx^*) + (\langle X, Y^* \rangle - \langle Y, X^* \rangle). \end{aligned} \quad (3.12)$$

The group  $H_{sc} \subset \text{Sp}(W)$  is generated by  $P_{sc}$  and an element  $w$  of order 4, giving a simple reflection in the Weyl group which normalizes  $M$  (a Levi factor of  $P_{sc}$ ).

To define  $w$  in  $\text{Sp}(W)$ , we need to choose a polarization  $I$  of  $J_{\mathbb{O}}$  with  $\det(I) = 1$  and  $I > 0$  in  $J_{\mathbb{O}} \otimes \mathbb{R}$  [EG; Ch. 2]. Since  $M$  acts transitively on polarizations over  $\mathbb{Q}$ , there is no loss of generality in taking  $I$  to be the identity matrix in  $J_{\mathbb{O}}$ . This gives a positive-definite bilinear form on  $J_{\mathbb{O}}$ , defined by

$$\langle A, B \rangle = -(A, B, I) + (A, I, I)(B, I, I)/4. \quad (3.13)$$

If  $I$  is the identity matrix, then  $\langle A, B \rangle = \text{Tr}(AB) = \text{Tr}(A \circ B) = \text{Tr}(BA)$ . This form defines an identification  $J_{\mathbb{O}} \cong J_{\mathbb{O}}^*$ . With this identification, we define  $w$ , which depends on  $I$  and satisfies  $w^2 = -1$ , by

$$w(y, Y, Y^*, y^*) = (-y^*, -Y^*, Y, y). \quad (3.14)$$

Then  $H_{sc} = \langle P_{sc}, w \rangle$  in  $\text{Sp}(W)$ . The element  $w$  acts by inversion on the center  $\mathbb{G}_m$  of  $M$ , and  $w^2$  is an involution in the center of  $M$ , which generates the center

$\mu_2$  of  $H_{sc}$ . In the quotient  $H = H_{sc}/\mu_2$ , the image  $\bar{w}$  of  $w$  has order 2, and gives the Cartan involution of  $\text{Lie}(H)$  over  $\mathbb{R}$ .

The adjoint group  $H$  has the maximal parabolic

$$P = P_{sc}/\mu_2 = MN, \tag{3.15}$$

with isomorphic Levi factor ( $M/\mu_2 \cong M$ ), but with a different conjugation action of  $M$  on  $N \cong J_{\mathbb{O}}$ :

$$mA m^{-1} = m(A). \tag{3.16}$$

Note that this action is faithful.

We can use the Coxeter order  $\mathcal{R} \subset \mathbb{O}$  to give a model for  $H_{sc}$  over  $\mathbb{Z}$  with good reduction at all primes  $p$  [Gr]. Let  $J_{\mathcal{R}} \subset J_{\mathbb{O}}$  be the lattice consisting of all elements with  $a, b, c$  in  $\mathbb{Z}$ , and  $x, y, z$  in  $\mathcal{R}$ . Then

$$W_{\mathbb{Z}} = \mathbb{Z} \oplus J_{\mathcal{R}} \oplus J_{\mathcal{R}}^* \oplus \mathbb{Z}^* \tag{3.17}$$

is a lattice in  $W$ , where  $J_{\mathcal{R}}^* = \text{Hom}(J_{\mathcal{R}}, \mathbb{Z}) \cong J_{\mathcal{R}}$  such that [EG], and  $\mathbb{Z}^* = \text{Hom}(\mathbb{Z}, \mathbb{Z}) \cong \mathbb{Z}$ . The stabilizer of  $W_{\mathbb{Z}}$  gives a desired model  $H_{sc}(\mathbb{Z}) \subset Sp_{56}(\mathbb{Z})$ . Then  $\text{Lie}(H_{sc}/\mathbb{Z}) \subset_2 \text{Lie}(H/\mathbb{Z})$  as lattices in  $\text{Lie}(H)$ . If we normalize the Killing form so that the determinant of  $\text{Lie}(H_{sc}/\mathbb{Z})$  is 2, then  $\text{Lie}(H/\mathbb{Z})$  is the dual lattice.

#### 4. Dual pair $G \times G'$

We now give two constructions of the dual pair  $G \times G' = \text{Aut}(\mathbb{O}) \times PGSp_6$  in  $H$  over  $\mathbb{Q}$ . The first uses the relative root system, and the second our construction of  $H$  as a group generated by  $P$  and  $\bar{w}$ .

Over  $\mathbb{Q}$ , the simple group  $H$  has index [Ti; pgs 59–60]

$$\tag{4.1}$$

and relative root system  $\Phi$  of type  $C_3$ . Let  $S$  be a maximal split torus of dimension 3 in  $H$ . The derived group of the centralizer  $C(S)$  (the semi-simple anisotropic kernel) is isomorphic to the group (see [Gr])

$$\begin{aligned} \text{Spin}_8(\mathbb{O}) = \{(\gamma_1, \gamma_2, \gamma_3) \in \text{GL}(\mathbb{O})^3 \mid \mathbb{N}(\gamma_i x) = \mathbb{N}(x), \\ \text{Tr}(\gamma_1 x \cdot \gamma_2 y \cdot \gamma_3 z) = \text{Tr}(xyz)\}. \end{aligned} \tag{4.2}$$

The group has 3 orthogonal representations  $V_1, V_2, V_3$  of dimension 8, via the action of  $\gamma_1, \gamma_2, \gamma_3$  on  $\mathbb{O}$ .

The 6 long root spaces  $\text{Lie}(H)_\alpha$  ( $\alpha = \pm 2e_i$ ) for  $S$  have dimension 1, and trivial action of  $\text{Spin}_8(\mathbb{O})$ . The 12 short root spaces  $\text{Lie}(H)_\alpha$  ( $\alpha = \pm e_i \pm e_j$ ) for  $S$  have dimension 8, and  $\text{Spin}_8(\mathbb{O})$  acts on  $\text{Lie}(H)_{\pm e_i \pm e_j}$  by the representation  $V_k$ , ( $i \neq j \neq k$ ).

From this viewpoint  $G$  is the subgroup of all triples  $(\gamma, \gamma, \gamma)$  in  $\text{Spin}_8(\mathbb{O})$  with  $\gamma$  in  $\text{Aut}(\mathbb{O})$ . Since  $\gamma(1) = 1$ , the restriction of each  $V_i$  to  $G$  is isomorphic to  $\mathbb{Q} \oplus V$ . Hence  $\text{Lie}(H)_\alpha^G$  has dimension 1 for all  $\alpha \in \Phi$ , and the centralizer of  $G$  in  $H$  is a split group of type  $C_3$ . Since the roots  $\Phi$  give a basis for the character group of  $S$ ,  $G'$  is of adjoint type, and  $G' = PGS_{p_6}$ . Conversely, the centralizer of  $G'$  is contained in  $\text{Spin}_8(\mathbb{O})$ , and fixes a vector in each 8-dimensional representation  $V_i$ . This shows that the centralizer of  $G'$  is contained in  $G$ , hence equal to  $G$ .

The following alternative construction of the closed subgroup  $G \times G'$  of  $H$  uses our construction in the previous section. The group  $G = \text{Aut}(\mathbb{O})$  is a subgroup of  $M \subset P$ , via the action on the matrix entries  $x, y, z$  of  $A$  in  $J_{\mathbb{O}}$ . Let  $U \subset N$  be the group fixed by this action, consisting of matrices with rational entries  $x, y, z$ . Then  $U$  has dimension 6 over  $\mathbb{Q}$ . We have an embedding of  $L = \text{GL}_3$  into  $M$  given by

$$\det(g)^{-1} gAg^t, \quad (4.3)$$

where  $\det(g)$  and  $g^t$  denote the determinant and the transpose of the  $3 \times 3$  matrix  $g$ . Note that the restriction of  $\lambda$  to  $L \cong \text{GL}_3$  is  $\det(g)^{-1}$ . The image stabilizes the subgroup  $U$ , and the semi-direct product

$$Q = LU \quad (4.4)$$

is a subgroup of  $P$ , commuting with  $G$ .

Assume that the polarization  $I$  defining  $w$  has rational entries, (for example, take  $I$  the identity matrix). Then the image  $\bar{w}$  of  $w$  in  $H$  commutes with  $G$  and normalizes  $L$ . Moreover,

$$G' = PGS_{p_6} = \langle Q, \bar{w} \rangle \quad (4.5)$$

in  $H$ . This gives the dual pair  $G \times G'$  in  $H$ .

### 3. Real correspondences

Let  $H(\mathbb{R})$  be the adjoint algebraic group of type  $E_7$  whose connected component is the group of conformal transformations of the exceptional symmetric domain. We have the dual pair

$$G(\mathbb{R}) \times G'(\mathbb{R}) = \text{Aut}(\mathbb{O} \otimes \mathbb{R}) \times PGS_{p_6}(\mathbb{R}) \quad (0.1)$$

in  $H(\mathbb{R})$  with  $G(\mathbb{R})$  the compact form of  $G_2$ .

Let  $\hat{\Pi}$  be the minimal representation of  $H(\mathbb{R})$ . In this chapter we show that

$$\Pi|_{G(\mathbb{R}) \times G'(\mathbb{R})} = \hat{\oplus}_{\pi} \pi \otimes \Theta(\pi), \tag{0.2}$$

where the sum is taken over all finite dimensional representations of  $G(\mathbb{R})$  and  $\Theta(\pi)$  is an irreducible representation whose restriction to  $\mathrm{Sp}_6(\mathbb{R})$  is a sum of a holomorphic and an anti-holomorphic discrete series representation. The lift  $\pi \mapsto \Theta(\pi)$  is functorial for the inclusion of dual groups  $G_2(\mathbb{C}) \rightarrow \mathrm{Spin}_7(\mathbb{C})$  (note that  $G_2$  is the stabilizer of a generic vector in the spin-module of  $\mathrm{Spin}_7$ ).

1. *Minimal representation of  $H_{sc}(\mathbb{R})$*

Let  $H_{sc}(\mathbb{R})$  be the simply connected group of type  $E_{7,3}$  over  $\mathbb{R}$ . Its real rank is 3 and the reduced root system is  $C_3$ . Let  $e_i - e_j$ ,  $(1 \leq i < j \leq 3)$  and  $e_i + e_j$ ,  $(1 \leq i \leq j \leq 3)$  be the standard set of positive roots. The root spaces corresponding to  $e_i + e_j$ ,  $(1 \leq i < j \leq 3)$  are 8-dimensional and can be identified with  $\mathbb{O} \otimes \mathbb{R}$ . The root spaces corresponding to strongly orthogonal  $2e_i$  are one-dimensional, hence we have an embedding

$$\mathrm{SL}_2(\mathbb{R}) \times \mathrm{SL}_2(\mathbb{R}) \times \mathrm{SL}_2(\mathbb{R}) \subset H_{sc}(\mathbb{R}). \tag{1.1}$$

Choose  $K_{sc}(\mathbb{R})$ , a maximal compact subgroup of  $H_{sc}(\mathbb{R})$ , such that

$$Z_1(\mathbb{R}) \times Z_2(\mathbb{R}) \times Z_3(\mathbb{R}) = K_{sc}(\mathbb{R}) \cap \mathrm{SL}_2(\mathbb{R}) \times \mathrm{SL}_2(\mathbb{R}) \times \mathrm{SL}_2(\mathbb{R}) \tag{1.2}$$

is a compact maximal Cartan subgroup of  $\mathrm{SL}_2(\mathbb{R}) \times \mathrm{SL}_2(\mathbb{R}) \times \mathrm{SL}_2(\mathbb{R})$ . Let

$$Z(\mathbb{R}) = K_{sc}(\mathbb{R}) \cap \mathrm{SL}_2(\mathbb{R}), \tag{1.3}$$

where  $\mathrm{SL}_2(\mathbb{R}) \subset \mathrm{SL}_2(\mathbb{R}) \times \mathrm{SL}_2(\mathbb{R}) \times \mathrm{SL}_2(\mathbb{R})$  is diagonally embedded. Note that  $Z(\mathbb{R}) \cong \mathrm{SO}_2(\mathbb{R})$  is the center of  $K_{sc}(\mathbb{R})$ , and  $\langle \pm 1 \rangle \subset Z(\mathbb{R})$  is the center of  $H_{sc}(\mathbb{R})$ .

We henceforth denote by  $H_{sc}$ ,  $K_{sc}$ ,  $Z \dots$  the complexifications of  $H_{sc}(\mathbb{R})$ ,  $K_{sc}(\mathbb{R})$ ,  $Z(\mathbb{R}) \dots$ . Let  $\mathfrak{h}$  and  $\mathfrak{k}$  be the Lie algebras of  $H_{sc}$  and  $K_{sc}$ . Then

$$\mathfrak{h} = \mathfrak{p}^- \oplus \mathfrak{k} \oplus \mathfrak{p}^+, \tag{1.4}$$

where  $\mathfrak{p}^{\pm}$  are two fundamental 27-dimensional representations of the exceptional Lie algebra  $\mathfrak{e}_6 = [\mathfrak{k}, \mathfrak{k}]$  of type  $E_6$ . Under the action of  $Z_1 \times Z_2 \times Z_3$ ,  $\mathfrak{p}^+$  decomposes as a sum of root spaces  $\gamma_i + \gamma_j$ ,  $(1 \leq i \leq j \leq 3)$ .

Let  $e^-, z, e^+$  be a standard basis of  $\mathfrak{sl}(2) \subset \mathfrak{sl}(2) \oplus \mathfrak{sl}(2) \oplus \mathfrak{sl}(2) \subset \mathfrak{h}$  such that  $z$  spans the Lie algebra of  $Z$ ,  $e^- \in \mathfrak{p}^-$  and  $e^+ \in \mathfrak{p}^+$ .

Let  $\lambda^+$  be the highest weight of the irreducible  $\mathfrak{e}_6$ -module  $\mathfrak{p}^+$ . Let  $E(n)$  be the irreducible representation of  $\mathfrak{e}_6$  with highest weight  $n\lambda^+$ . Since  $\mathfrak{k} = \mathfrak{e}_6 \oplus \mathbb{C}z$ , let  $E(n, k)$  be the representation of  $\mathfrak{k}$  such that the restriction to  $\mathfrak{e}_6$  is isomorphic to  $E(n)$  and  $z$  acts via the scalar  $k$ . Let  $\Pi^+$  be the irreducible  $(\mathfrak{h}, K_{sc})$ -module corresponding to a holomorphic representation of  $H_{sc}(\mathbb{R})$ , with  $K_{sc}$ -types [W1]

$$\Pi^+|_{K_{sc}} = \oplus_{n \geq 0} E(n, 2n + 12). \tag{1.5}$$

The annihilator of  $\Pi^+$  in the enveloping algebra of  $\mathfrak{h}$  is Joseph's ideal. In particular, the Gelfand–Kirillov dimension of  $\Pi^+$  is the smallest amongst non-trivial modules. There is also an anti-holomorphic module  $\Pi^-$ , contragredient to  $\Pi^+$ . By (1.5) the center  $\langle \pm 1 \rangle \subset Z(\mathbb{R})$  acts trivially on  $\Pi^-$  and  $\Pi^+$ .

Let  $\hat{\Pi}^-$  and  $\hat{\Pi}^+$  denote the unitary completion of  $\Pi^-$  and  $\Pi^+$ . Since  $H_{sc}(\mathbb{R})$  and  $H(\mathbb{R})$  are related by the exact sequence

$$1 \rightarrow \langle \pm 1 \rangle \rightarrow H_{sc}(\mathbb{R}) \rightarrow H(\mathbb{R}) \rightarrow \mathbb{R}^\times / (\mathbb{R}^\times)^2 \rightarrow 1, \quad (1.6)$$

it follows that there exist unique representation  $\hat{\Pi}$  of  $H(\mathbb{R})$  such that

$$\hat{\Pi}|_{H_{sc}(\mathbb{R})} = \hat{\Pi}^+ \oplus \hat{\Pi}^-. \quad (1.7)$$

It is precisely this representation that we call the minimal representation of  $H(\mathbb{R})$ .

## 2. Dual pairs

We now describe several dual pairs in  $\mathfrak{h}$  using Jordan algebras. Note that

$$x \circ y = \frac{1}{2}[[x, e^-], y] \quad (2.1)$$

gives a Jordan product on  $\mathfrak{p}^+$ . Then  $(\mathfrak{p}^+, \circ)$  is isomorphic to the exceptional Jordan algebra of  $3 \times 3$  hermitian matrices

$$\begin{pmatrix} d_1 & z_{1,2} & \bar{z}_{1,3} \\ \bar{z}_{1,2} & d_2 & z_{2,3} \\ z_{1,3} & \bar{z}_{2,3} & d_3 \end{pmatrix}, \quad (2.2)$$

with coefficients in the octonion algebra over  $\mathbb{C}$ . Under this isomorphism, the 1-dimensional root spaces  $2\gamma_i$ , ( $1 \leq i \leq 3$ ) are given by diagonal matrices such that  $d_j = 0$  if  $j \neq i$ , and the 8-dimensional root spaces  $\gamma_i + \gamma_j$ , ( $i < j$ ) are given by off-diagonal matrices such that  $z_{k,l} = 0$  if  $\{k, l\} \neq \{i, j\}$ .

Let  $\mathfrak{q}^+ \subset \mathfrak{p}^+$  be a Jordan subalgebra containing  $e^+$ . Let

$$\mathfrak{a} = C_{\mathfrak{h}}(\mathfrak{q}^+). \quad (2.3)$$

Assume, conversely, that  $\mathfrak{q}^+$  is the set of all elements in  $\mathfrak{p}^+$  annihilated by  $\mathfrak{a}$ . Let  $\mathfrak{u} = C_{\mathfrak{h}}(\mathfrak{a})$ , and  $\mathfrak{q}^- \subset \mathfrak{p}^-$  such that  $\mathfrak{q}^+ = [e^+, [e^+, \mathfrak{q}^-]]$ . Then

$$\mathfrak{b} = \mathfrak{q}^- \oplus \mathfrak{u} \oplus \mathfrak{q}^+ \quad (2.4)$$

is the centralizer of  $\mathfrak{a}$  in  $\mathfrak{b}$ . Obviously, the converse is also true, i.e.  $\mathfrak{a} \times \mathfrak{b}$  is a dual reductive pair.

Some of the possible cases are:

$\dim \mathfrak{q}^+$	$\mathfrak{a}$	$\mathfrak{b}$	$\mathfrak{u}$	
1	$\mathfrak{f}_4$	$\mathfrak{sl}(2)$	$u(1)$	(2.5)
3	$\mathfrak{d}_4$	$\mathfrak{sl}(2) \oplus \mathfrak{sl}(2) \oplus \mathfrak{sl}(2)$	$u(1) \oplus u(1) \oplus u(1)$	
6	$\mathfrak{g}_2$	$\mathfrak{sp}(6)$	$u(3),$	

where the subalgebra  $\mathfrak{q}^+$  is given respectively by  $3 \times 3$  scalar, diagonal and symmetric matrices with coefficients in  $\mathbb{C}$ .

### 3. Correspondences

In this section we restrict the representation  $\Pi^+$  to the dual pairs  $A(\mathbb{R}) \times B(\mathbb{R})$  given by (2.5), with  $A(\mathbb{R})$  compact.

We start with  $A(\mathbb{R}) = F_4(\mathbb{R})$ . The 27-dimensional module  $\mathfrak{p}^+$  decomposes  $1+26$ , under the action of  $F_4(\mathbb{R})$ . Let  $\lambda$  the highest weight of the 26-dimensional summand, and let  $F(n)$  be the irreducible representation of  $F_4(\mathbb{R})$  with highest weight  $n\lambda$ . By Thm. 6.1 in [HPS]

$$E(n) = \bigoplus_{m \leq n} F(m). \tag{3.1}$$

**PROPOSITION 3.2.** *Consider the dual pair  $F_4(\mathbb{R}) \times \mathrm{SL}_2(\mathbb{R})$ . Then*

$$\Pi^+|_{F_4(\mathbb{R}) \times \mathfrak{sl}(2)} = \bigoplus_{n \geq 0} F(n) \otimes d(2n + 12),$$

where  $d(n)$  is the irreducible  $(\mathfrak{sl}(2), Z)$ -module corresponding to the holomorphic discrete series of  $\mathrm{SL}_2(\mathbb{R})$  with the minimal  $Z$ -type  $n$ .

*Proof.* By (3.1) one can write

$$\Pi^+|_{F_4(\mathbb{R}) \times \mathfrak{sl}(2)} = \bigoplus_{n \geq 0} F(n) \otimes V_n,$$

where  $V_n$  are certain  $(\mathfrak{sl}(2), Z)$ -modules. Since  $F(n)$  appears in  $E(k, 2k + 12)$  only for  $k = n, n + 1, \dots$ ,  $Z$ -types of  $V_n$  are  $2n + 12, 2n + 14, \dots$  and are one-dimensional. The proposition is proved.

Next, consider the case  $A(\mathbb{R}) = D_4(\mathbb{R})$ . Then  $D_4(\mathbb{R})$ -invariant subspaces of  $\mathfrak{p}^+$  are precisely the root spaces. The three 8-dimensional root spaces are 3 different fundamental 8-dimensional representations of  $D_4(\mathbb{R})$ . Let  $\lambda_i, (1 \leq i \leq 3)$  be the highest weight of the fundamental representation given by the root space  $\gamma_j + \gamma_k$ , where  $\{j, k\} = \{1, 2, 3\} \setminus \{i\}$ . Let  $D(a_1, a_2, a_3)$  be the irreducible representation of  $D_4(\mathbb{R})$  with a highest weight  $a_1\lambda_1 + a_2\lambda_2 + a_3\lambda_3$ .

**PROPOSITION 3.3.** *Consider the dual pair  $D_4(\mathbb{R}) \times \mathrm{SL}_2(\mathbb{R})^3$ . Then*

$$\begin{aligned} \Pi^+|_{D_4(\mathbb{R}) \times \mathfrak{sl}(2)^3} &= \bigoplus_{a_1, a_2, a_3 \geq 0} D(a_1, a_2, a_3) \otimes \\ &d(a_2 + a_3 + 4) \otimes d(a_1 + a_3 + 4) \otimes d(a_1 + a_2 + 4), \end{aligned}$$

where  $d(n)$  is the irreducible  $(\mathfrak{sl}(2), Z)$ -module corresponding to the holomorphic discrete series of  $\mathrm{SL}_2(\mathbb{R})$  with the minimal  $Z$ -type  $n$ .

*Proof.* We want to decompose  $E(n, 2n)$  with respect to the action of  $D_4 \times Z_1 \times Z_2 \times Z_3$ . Write

$$E(n, 2n) = \Gamma(\mathcal{L}^{\otimes n}),$$

where  $\mathcal{L}$  is a line bundle on the flag variety. Since  $E(1, 2) \cong \mathfrak{p}^+$ , we know how to decompose  $E(1, 2)$ . Let  $v_i \in \Gamma(\mathcal{L})$  be highest weight vectors of the three 8-dimensional representations with the highest weights  $\lambda_i$ . Let  $w_i \in \Gamma(\mathcal{L})$  be nonzero vectors with weights  $2\gamma_i$ . Let  $a_i$  and  $r_i$  ( $i = 1, 2, 3$ ), be nonnegative integers such that

$$a_1 + a_2 + a_3 + r_1 + r_2 + r_3 = n.$$

Then

$$v_1^{a_1} v_2^{a_2} v_3^{a_3} w_1^{r_1} w_2^{r_2} w_3^{r_3} \in \mathcal{L}^{\otimes n}$$

generates a  $D_4$ -module isomorphic to  $D(a_1, a_2, a_3)$ , with a  $Z_1 \times Z_2 \times Z_3$ -type

$$(a_2 + a_3 + 2r_1, a_1 + a_2 + 2r_2, a_1 + a_2 + 2r_3).$$

Note that different choices of  $a_i$  and  $r_i$  produce non-isomorphic modules. We claim that these modules give a complete decomposition of  $E(n, 2n)$ . Indeed, let

$$x = n + 1 - (a_1 + a_2 + a_3).$$

Since  $E(n) = \bigoplus_{m \leq n} F(m)$  it follows from Proposition 4.7 that the multiplicity of  $D(a_1, a_2, a_3)$  in  $E(n, 2n)$  is  $x(x+1)/2$ . Since

$$\frac{x(x+1)}{2} = \#\{(r_1, r_2, r_3) \mid r_1 + r_2 + r_3 = x - 1\},$$

the claim follows.

Write

$$\Pi^+|_{D_4(\mathbb{R}) \times \mathfrak{sl}(2) + \mathfrak{sl}(2) + \mathfrak{sl}(2)} = \bigoplus_{a_1, a_2, a_3 \geq 0} D(a_1, a_2, a_3) \otimes V_{a_1, a_2, a_3}.$$

Taking into account the additional shift by 12, it follows that  $Z_1 \times Z_2 \times Z_3$ -types of  $V_{a_1, a_2, a_3}$  are

$$(a_2 + a_3 + 2r_1 + 4, a_1 + a_3 + 2r_2 + 4, a_2 + a_3 + 2r_3 + 4),$$

and they are one-dimensional. The proposition is proved.

Finally, we consider the case  $A(\mathbb{R}) = G_2(\mathbb{R})$ . Let  $\omega_1$  and  $\omega_2$  be the fundamental weights for  $G_2$ , such that  $\omega_1$  is the highest weight of the 7-dimensional representation. Let  $W(k_1, k_2)$  be the irreducible representation of  $G_2(\mathbb{R})$  with highest weight  $k_1\omega_1 + k_2\omega_2$ .

Note that  $B(\mathbb{R}) = \mathrm{Sp}_6(\mathbb{R})$ , and the reduced root system of  $H(\mathbb{R})$  restricts to a root system of  $\mathrm{Sp}_6(\mathbb{R})$ . Also, let  $U(3, \mathbb{R})$  be a maximal compact subgroup of  $\mathrm{Sp}_6(\mathbb{R})$  given by

$$U(3, \mathbb{R}) = K_{sc}(\mathbb{R}) \cap \mathrm{Sp}_6(\mathbb{R}). \tag{3.4}$$

We identify irreducible representations of the group  $U(3, \mathbb{R})$  with their highest weights  $l_1\gamma_1 + l_2\gamma_2 + l_3\gamma_3$ , ( $l_1 \geq l_2 \geq l_3$ ) with respect to the maximal Cartan subgroup  $Z_1(\mathbb{R}) \times Z_2(\mathbb{R}) \times Z_2(\mathbb{R})$ .

**THEOREM 3.5.** *Consider the dual pair  $G_2(\mathbb{R}) \times \mathrm{Sp}_6(\mathbb{R})$ . Then*

$$\Pi^+|_{G_2(\mathbb{R}) \times \mathfrak{sp}(6)} = \bigoplus_{k_1, k_2 \geq 0} W(k_1, k_2) \otimes d(k_1, k_2),$$

where  $d(k_1, k_2)$  is the irreducible  $(\mathfrak{sp}(6), U(3))$ -module corresponding to the holomorphic discrete series representation of  $\mathrm{Sp}_6(\mathbb{R})$  with infinitesimal character

$$(k_1 + 2k_2 + 3)e_1 + (k_1 + k_2 + 2)e_2 + (k_2 + 1)e_3$$

and the minimal  $U(3)$ -type

$$(k_1 + 2k_2 + 4)\gamma_1 + (k_1 + k_2 + 4)\gamma_2 + (k_2 + 4)\gamma_3.$$

*Proof.* Write

$$\Pi^+|_{G_2(\mathbb{R}) \times \mathfrak{sp}(6)} = \bigoplus_{k_1, k_2 \geq 0} W(k_1, k_2) \otimes V_{k_1, k_2}.$$

By [HPS; Theorem 5.4] the infinitesimal character of  $V_{k_1, k_2}$  is  $(k_1 + 2k_2 + 3)e_1 + (k_1 + k_2 + 2)e_2 + (k_2 + 1)e_3$ . It is  $Z$ -admissible, with positive  $Z$ -types. Hence it is a direct sum of finitely many unitary lowest weight modules.

**LEMMA 3.6.** *In addition to  $d(k_1, k_2)$  one has the following unitary lowest weight modules with infinitesimal character  $(k_1 + 2k_2 + 3)e_1 + (k_1 + k_2 + 2)e_2 + (k_2 + 1)e_3$ :*

- (1)  $k_2 = 0$  and  $k_1 \neq 0$ . There is a module with the minimal  $Z$ -type  $2k_1 + 10$ .
- (2)  $k_1 = k_2 = 0$ . There are three modules. Their minimal  $Z$ -types are 0, 6 and 10.

Note that the minimal  $Z$ -type of  $d(k_1, k_2)$  is  $2k_1 + 4k_2 + 12$ , hence it is strictly bigger than the minimal  $Z$ -type of any other modules with the same infinitesimal character.

*Proof.* This follows from the classification of unitary lowest weight modules [EHW].

By Proposition 4.8,  $W(k_1, 0)$  does not appear in  $D(a_1, a_2, a_3)$  unless  $k_1 \leq a_1 + a_2 + a_3$ . It follows from Proposition 4.2 that the minimal  $Z$ -type of  $V_{k_1,0}$  is greater than  $2k_1 + 12$ . It follows from the lemma that in all cases  $V_{k_1,k_2}$  is a finite multiple of  $d(k_1, k_2)$ . This implies that the minimal  $Z$ -type of  $V_{k_1,k_2}$  is  $2k_1 + 4k_2 + 12$ , so by Proposition 3.3, if  $W(k_1, k_2)$  is contained in  $D(a_1, a_2, a_3)$ , then

$$a_1 + a_2 + a_3 \geq k_1 + 2k_2.$$

Hence, the multiplicity of

$$(k_2 + 4)\gamma_1 + (k_1 + k_2 + 4)\gamma_2 + (k_1 + 2k_2 + 4)\gamma_3,$$

the lowest weight of the minimal  $U(3)$ -type of  $d(k_1, k_2)$  in  $V_{k_1,k_2}$ , is equal to the multiplicity of  $W(k_1, k_2)$  in  $D(k_1 + k_2, k_2, 0)$ . And this is one by Proposition 4.8. Hence the minimal  $U(3)$ -type appears with multiplicity one and this implies that  $V_{k_1,k_2} \cong d(k_1, k_2)$ .

Let  $\bar{d}(k_1, k_2)$  be the contragredient of  $d(k_1, k_2)$ . It corresponds to an anti-holomorphic representation of  $Sp_6(\mathbb{R})$ . Since

$$1 \rightarrow \langle \pm 1 \rangle \rightarrow Sp_6(\mathbb{R}) \rightarrow PGSp_6(\mathbb{R}) \rightarrow \mathbb{R}^\times / (\mathbb{R}^\times)^2 \rightarrow 1, \tag{3.7}$$

there exists unique irreducible discrete series representation  $\mathcal{D}(k_1, k_2)$  of  $PGSp_6(\mathbb{R})$ , which is the unitary completion of

$$d(k_1, k_2) \oplus \bar{d}(k_1, k_2). \tag{3.8}$$

This observation gives a proof of the following.

**COROLLARY 3.9.** *Let  $\hat{\Pi}$  be the minimal representation of  $H(\mathbb{R})$ . Then*

$$\hat{\Pi}|_{G(\mathbb{R}) \times PGSp_6(\mathbb{R})} = \hat{\bigoplus}_{k_1, k_2 \geq 0} W(k_1, k_2) \otimes \mathcal{D}(k_1, k_2).$$

The lift

$$W(k_1, k_2) \rightarrow \mathcal{D}(k_1, k_2) \tag{3.10}$$

is functorial for the inclusion of dual groups  $G_2(\mathbb{C}) \rightarrow Spin_7(\mathbb{C})$ . This is shown in [HPS].

#### 4. Branching formulas

In this section we work out the branching laws used in the previous section. Let  $(a_1, \dots, a_n)$  be the standard coordinates [Bu] for the root system of type  $B_n$ , with

$$a_1 \geq \dots \geq a_n \geq 0 \tag{4.1}$$

a dominant Weyl chamber. Also, let  $(b_1, \dots, b_n)$  be the standard coordinates for the root system of type  $D_n$ , with

$$b_1 \geq \dots \geq b_{n-1} \geq |b_n|, \tag{4.2}$$

a dominant Weyl chamber. Recall that in both cases a dominant weight represents a highest weight of a finite dimensional representation if the coefficients are in  $\frac{1}{2}\mathbb{Z}$  but their differences are in  $\mathbb{Z}$ .

*4.3 Branching  $B_n \downarrow D_n$ . Let  $\pi(\lambda)$  be an irreducible representation of  $B_n$  with the highest weight  $\lambda = (a_1, \dots, a_n)$ . Let  $\pi(\mu)$  be an irreducible representation of  $D_n$  with the highest weight  $\mu = (b_1, \dots, b_n)$ . Then the multiplicity of  $\pi(\mu)$  in  $\pi(\lambda)$  is 0 or 1. It is 1 if and only if  $a_i - b_i \in \mathbb{Z}$  and*

$$a_1 \geq b_1 \geq a_2 \geq b_2 \geq \dots \geq a_n \geq |b_n|.$$

*4.4 Branching  $D_n \downarrow B_{n-1}$ . Let  $\pi(\lambda)$  be an irreducible representation of  $D_n$  with the highest weight  $\lambda = (a_1, \dots, a_n)$ . Let  $\pi(\mu)$  be an irreducible representation of  $B_{n-1}$  with the highest weight  $\mu = (b_1, \dots, b_{n-1})$ . Then the multiplicity of  $\pi(\mu)$  in  $\pi(\lambda)$  is 0 or 1. It is 1 if and only if  $a_i - b_i \in \mathbb{Z}$  and*

$$a_1 \geq b_1 \geq a_2 \geq b_2 \geq \dots \geq b_{n-1} \geq |a_n|.$$

Let  $\lambda$  be the highest weight of the 26-dimensional representation of  $F_4$ . Let  $F(n)$  be the irreducible representation with the highest weight  $n\lambda$ .

*4.5 Branching  $F_4 \downarrow B_4$ . The restriction of  $F(n)$  to  $B_4$  decomposes with multiplicities 0 or 1. It is 1 only for  $\pi(\mu)$  with*

$$\mu = (y + x, x, x, x)$$

and  $2x + y \leq n$ .

The branching laws 4.3 and 4.4 are well known, and 4.5 is in [Le; Thm. 8]. This reference also contains proofs of 4.3 and 4.4.

Recall that  $D_4$  has three 8-dimensional representations. Let  $\lambda_i, i = 1, 2, 3$ , be their highest weights. Let  $D(a_1, a_2, a_3)$  be the irreducible representation with highest weight  $a_1\lambda_1 + a_2\lambda_2 + a_3\lambda_3$ . In terms of (4.2) this highest weight is

$$\left( a_1 + \frac{a_2 + a_3}{2}, \frac{a_2 + a_3}{2}, \frac{a_2 + a_3}{2}, \frac{a_2 - a_3}{2} \right). \tag{4.6}$$

*4.7 Branching  $F_4 \downarrow D_4$ . The representation  $F(n)$  decomposes as a sum of  $D(a_1, a_2, a_3)$  with multiplicities*

$$(n + 1) - (a_1 + a_2 + a_3).$$

*Proof.* We know that the restriction of  $F(n)$  to  $B_4$  is a sum of representations with highest weights

$$(y + x, x, x, x),$$

$2x + y \leq n$ . Restricting further down to  $D_4$  we get a sum of all representations with highest weights  $(u_1, u_2, u_3, u_4)$  such that

$$y + x \geq u_1 \geq x \geq u_2 \geq x \geq u_3 \geq x \geq |u_4|.$$

It follows that  $u_2 = u_3 = x$  and the representation can be written as

$$D(u_1 - x, x - u_4, x + u_4),$$

by (4.6). Now

$$D(u_1 - x, x - u_4, x + u_4) = D(a_1, a_2, a_3)$$

implies that  $2x = a_2 + a_3$  and  $u_1 = a_1 + x$ . Since  $y + x \geq u_1$ , we have  $y \geq a_1$ . Hence the multiplicity of  $D(a_1, a_2, a_3)$  in  $F(n)$  is the number of integers  $y$  such that  $y \geq a_1$  and  $y + a_2 + a_3 \leq n$ . Clearly, this number is  $(n + 1) - (a_1 + a_2 + a_3)$ .

#### PROPOSITION 4.8.

- (1) *The multiplicity of  $W(k_1, k_2)$  in  $D(k_1 + k_2, k_2, 0)$  is 1.*
- (2) *The multiplicity of  $W(k_1, 0)$  in  $D(a_1, a_2, a_3)$ , is 0 unless  $a_1 + a_2 + a_3 \geq k_1$ .*

*Proof.* Let  $\mu_1$ ,  $\mu_2$  and  $\mu_3$  be the fundamental weights for  $B_3$  such that  $\mu_1$  is the highest weight of the standard 7-dimensional representation and  $\mu_3$  is the highest weight of the 8-dimensional spin-representation. Let  $B(m_1, m_2, m_3)$  be the irreducible representation with highest weight  $m_1\mu_1 + m_2\mu_2 + m_3\mu_3$ . In terms of (4.1), this highest weight is

$$\left(m_1 + m_2 + \frac{m_3}{2}, m_2 + \frac{m_3}{2}, \frac{m_3}{2}\right).$$

#### LEMMA 4.9.

- (1) *The multiplicity of  $W(k_1, k_2)$  in  $B(j, 0, k_2)$ ,  $j \leq k_1 + k_2$ , is 0 or 1. It is 1 precisely when  $j = k_1 + k_2$ .*
- (2) *The multiplicity of  $W(k_1, 0)$  in  $B(m_1, m_2, m_3)$ , is 0 or 1. It is 1 precisely when*

$$m_1 + m_2 + m_3 \geq k_1 \geq m_1 + m_2.$$

*Proof.* These are two easy, special cases of the formula given by McGovern, [MG; Thm. 3.4].

By (4.6) the highest weight of  $D(k_1 + k_2, k_2, 0)$  is

$$\left(k_1 + k_2 + \frac{k_2}{2}, \frac{k_2}{2}, \frac{k_2}{2}, \frac{k_2}{2}\right).$$

The branching  $D_4 \downarrow B_3$  implies that  $D(k_1 + k_2, k_2, 0)$  decomposes as a sum of representations with highest weights

$$\left(j + \frac{k_2}{2}, \frac{k_2}{2}, \frac{k_2}{2}\right),$$

with  $j \leq k_1 + k_2$ . These are  $B(j, 0, k_2)$  with  $j \leq k_1 + k_2$ . The first statement follows from the lemma.

Since the highest weight of  $D(a_1, a_2, a_3)$  is given by (4.6), the restriction to  $B_3$  consists of representations with highest weights  $(x, y, z)$  such that

$$a_1 + \frac{a_2 + a_3}{2} \geq x \geq \frac{a_2 + a_3}{2} \geq y \geq \frac{a_2 + a_3}{2} \geq z \geq \frac{a_2 - a_3}{2}.$$

It follows that  $y = (a_2 + a_3)/2$  and these are the representations

$$B\left(x - \frac{a_2 + a_3}{2}, \frac{a_2 + a_3}{2} - z, 2z\right).$$

The lemma implies that  $k_1 \leq x + z$ , and since  $x + z \leq a_1 + a_2 + a_3$ , the second statement follows. The proposition is proved.

#### 4. $p$ -adic correspondences

Our goal in this chapter is to understand the restriction of the minimal representation  $\Pi$  of  $H(\mathbb{Q}_p)$  to the closed subgroup  $G(\mathbb{Q}_p) \times G'(\mathbb{Q}_p)$ .

The minimal representation of a split, adjoint group  $H(\mathbb{Q}_p)$  of type  $D_n$  or  $E_n$  is an unramified representation whose Satake parameter is

$$s_{\min} = \varphi \begin{pmatrix} p^{1/2} & 0 \\ 0 & p^{-1/2} \end{pmatrix}, \tag{0.1}$$

where  $\varphi$  is a map

$$\varphi: \mathrm{SL}_2(\mathbb{C}) \rightarrow \hat{H}(\mathbb{C}) \tag{0.2}$$

corresponding to the subregular unipotent orbit in  $\hat{H}(\mathbb{C}) = H_{sc}(\mathbb{C})$ . The representation  $\Pi$  restricts to the irreducible representation of  $H_{sc}(\mathbb{Q}_p)$  constructed by Kazhdan and Savin in [KS]. On the space of Iwahori-fixed vectors in  $\Pi$ , the Iwahori–Hecke algebra of  $H_{sc}(\mathbb{Q}_p)$  acts via the reflection representation [Lu].

### 1. Parameters

In this section, we give a conjectural description of the irreducible representations  $\pi \otimes \pi'$  of  $G(\mathbb{Q}_p) \times G'(\mathbb{Q}_p)$  which occur as quotients of  $\Pi$ . This description is given in terms of the Langlands–Deligne–Lusztig–Vogan parametrization of irreducible representations, using admissible homomorphisms from Weil–Deligne group of  $\mathbb{Q}_p$  to the dual group. Even though this parametrization is still conjectural, in the next section we derive some implications which can be stated independently of the parametrization. We check some of these implications in Section 3.

We first review the parametrization, for  $G$  any semi-simple, split group of adjoint type over  $\mathbb{Q}_p$ . Let  $\hat{G}$  be the Langlands dual group, so  $\hat{G}(\mathbb{C})$  is semi-simple and simply-connected complex Lie group. The conjectural parameter of an irreducible, admissible, complex representation of  $G(\mathbb{Q}_p)$  is a pair  $(\varphi, \chi)$ , where

$$\varphi: W' \rightarrow \hat{G}(\mathbb{C}) \quad (1.1)$$

is an admissible homomorphism of the Weil–Deligne group  $W'$  of  $\mathbb{Q}_p$  [B1], and  $\chi$  is an irreducible complex representation of a finite group  $B_\varphi$  associated to  $\varphi$ .

We recall that  $\varphi$  is a continuous homomorphism of the Weil group  $W$  taking Frobenius elements to a semi-simple class, together with a nilpotent element  $N$  in  $\hat{\mathfrak{g}}$ , the Lie algebra of  $\hat{G}(\mathbb{C})$ , with  $\text{Ad}(w)(N) = \|w\|N$ . By the Jacobson–Morozov Theorem, giving a parameter  $\varphi$  as in (1.1) is equivalent to giving a continuous, semi-simple representation

$$\eta: W \times \text{SL}_2(\mathbb{C}) \rightarrow \hat{G}(\mathbb{C}), \quad (1.2)$$

with

$$\begin{cases} \varphi(w) = \eta \left( w, \begin{pmatrix} \|w\|^{1/2} & 0 \\ 0 & \|w\|^{-1/2} \end{pmatrix} \right) \\ \exp(N) = \eta \left( 1, \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \right). \end{cases} \quad (1.3)$$

Associated to  $\varphi$ , we have the finite group

$$A_\varphi = \pi_0(\text{Cent}(\eta)), \quad (1.4)$$

where  $\text{Cent}(\eta)$  is the algebraic subgroup of  $\hat{G}$  which centralizes the image of  $\eta$  and  $\pi_0$  denotes the corresponding group of connected components. If  $Z(\hat{G})$  is the center of  $\hat{G}$ , the inclusion  $Z(\hat{G}) \subseteq \text{Cent}(\varphi)$  induces a map (not necessarily injective)

$$Z(\hat{G}) \rightarrow A_\varphi. \quad (1.5)$$

The image is a normal subgroup, and we define  $B_\varphi$  as the quotient. Then an irreducible representation  $\pi$  of  $G(\mathbb{Q}_p)$  should correspond to a pair  $(\varphi, \chi)$ , where  $\chi$  is an irreducible representation of  $B_\varphi$ .

If  $G = G_2(\mathbb{Q}_p)$ , then  $\hat{G}(\mathbb{C}) = G_2(\mathbb{C})$ , and  $A_\varphi = B_\varphi$ . If  $G' = PGSp_6(\mathbb{Q}_p)$ , then  $\hat{G}'(\mathbb{C}) = Spin_7(\mathbb{C})$  and  $B_{\varphi'}$  is the quotient by the image of  $-1$ . The possible finite groups which arise are given by the following. Let  $\mu_k$  denote the cyclic group of  $k^{th}$  roots of 1, and  $S_k$  the symmetric group on  $k$  letters.

**PROPOSITION 1.6.**

- (1) If  $\varphi : W' \rightarrow G_2(\mathbb{C})$  is a parameter for  $G = G_2$ , then the group  $B_\varphi$  is isomorphic to  $\mu_3, S_3$ , or  $\mu_2^k$ , with  $0 \leq k \leq 3$ .
- (2) If  $\varphi' : W' \rightarrow Spin_7(\mathbb{C})$  is a parameter for  $G' = PGSp_6$  then the group  $B_{\varphi'}$  is isomorphic to  $\mu_2^k$ , with  $0 \leq k \leq 3$ . If  $a$  is the number of distinct orthogonal representations in the decomposition of the semi-simple  $W \times SL_2(\mathbb{C})$ -module  $V = \mathbb{C}^7$ , and  $b$  is the dimension of the subspace of  $Hom(W, \pm 1)$  spanned by the determinants of the orthogonal summands in  $V$ , then  $k = a - b - 1$ .

*Proof.* (1) Examples of subgroups  $Im(\eta)$  of  $G_2(\mathbb{C})$  with the given groups  $B_\varphi$  are given by the following table:

$Im(\eta)$	$B_\varphi$
$G_2$	1
$SL_3$	$\mu_3$
$SO_3$	$S_3$
$SO_4$	$\mu_2$
$T \rtimes \langle \pm 1 \rangle$	$\mu_2^2$
$T_2 \rtimes \langle \pm 1 \rangle$	$\mu_2^3$

Here  $T \cong GL_1^2$  is a maximal torus,  $T_2$  the subgroup of  $T$  killed by 2, and  $-1$  the central element in the Weyl group of  $T$ . The latter case  $(T_2 \rtimes \langle \pm 1 \rangle \cong \mu_2^3)$  can only be the image of  $\eta$  when  $p = 2$ . This list exhausts the possible groups  $B_\varphi$ , as we will see in the proof of Proposition 1.10.

(2) Examples of subgroups  $Im(\eta')$  of  $Spin_7(\mathbb{C})$  with the given groups  $B_{\varphi'}$  are given by the following table:

$Im(\eta')$	$A_{\varphi'}$	$B_{\varphi'}$
$Spin_7$	$\langle \pm 1 \rangle$	1
$Spin_6 = SL_4$	$\mu_4$	$\mu_2$
$T' \rtimes \langle \pm 1 \rangle$	$\mu_2^3$	$\mu_2^2$
$T_2' \rtimes \langle \pm 1 \rangle$	$\mu_2^4$	$\mu_2^3$

Again,  $T' \cong \mathrm{GL}_1^3$  is a maximal torus,  $T'_2$  the subgroup of  $T'$  killed by 2, and  $-1$  the central element in the Weyl group of  $T'$ . The last case ( $T'_2 \times \langle \pm 1 \rangle \cong \mu_2^4$ ) can only be the image of  $\eta'$  when  $p = 2$ .

To see that these are the only possibilities for  $B_{\varphi'}$ , and to verify the formula for  $k$ , we note that the representation  $V$  gives a parameter for  $\mathrm{Sp}_6$

$$\bar{\varphi}' : W' \rightarrow \mathrm{Spin}_7(\mathbb{C}) \rightarrow \mathrm{SO}_7(\mathbb{C}).$$

We can compute the component group  $A_{\bar{\varphi}'}$  using the results in [GP; Cor. 7.7], and find that

$$A_{\bar{\varphi}'} = B_{\bar{\varphi}'} \cong \mu_2^{a-1},$$

where  $a$  is the number of distinct orthogonal summands in the semi-simple representation  $V$ . But we have an exact sequence [GP; pg. 983]

$$\begin{aligned} 1 \rightarrow B_{\varphi'} \rightarrow B_{\bar{\varphi}'} \rightarrow \mathrm{Hom}(W, \pm 1), \\ x \mapsto \det(V^{x=-1}), \end{aligned}$$

so  $k = a - b - 1$  as claimed.

Now let

$$f : \hat{G}(\mathbb{C}) = G_2(\mathbb{C}) \rightarrow \hat{G}'(\mathbb{C}) = \mathrm{Spin}_7(\mathbb{C}) \quad (1.7)$$

be the inclusion, well defined up to conjugacy, that realizes  $G_2$  as the fixer of a non-isotropic line in the 8-dimensional spin representation of  $\mathrm{Spin}_7$ . If  $\varphi$  is a parameter for  $G$ , then

$$\varphi' = f \circ \varphi \quad (1.8)$$

is a parameter for  $G'$ . Moreover,  $f$  induces a map  $f_\varphi : A_\varphi \rightarrow A_{\varphi'}$ . Since  $A_\varphi = B_\varphi$  and  $B_{\varphi'}$  is the quotient of  $A_{\varphi'}$  by the image of  $-1$ , we get an induced map

$$f_\varphi : B_\varphi \rightarrow B_{\varphi'}. \quad (1.9)$$

**PROPOSITION 1.10.** *The map  $f_\varphi$  (1.9) is surjective, with kernel the Sylow 3-subgroup of  $B_\varphi$  (either 1 or  $\mu_3$ ).*

*Proof.* In the absence of the intelligent argument, we can prove this in a case by case manner, considering the connected component of the image of  $\eta$  in  $G_2(\mathbb{C})$ , which is a reductive subgroup  $C$ . Considering possible normalizers of  $C$ , and their action on  $V$ , we can compare  $B_\varphi$  with  $B_{\varphi'}$  computed in Proposition 1.6.

For example, assume that  $C$  has rank 2, i.e. it contains the maximal torus  $T$ . Then  $C$  is determined by its root system which is contained in the root system of

$G_2$ . Hence the possibilities for  $C$  are  $G_2, \text{SL}_3, \text{SO}_4, \text{GL}_{2,s}, \text{GL}_{2,l}$ , and  $T$ , where  $\text{SL}_3$  is spanned by long roots

$$\text{SO}_4 = \text{SL}_{2,s} \times \text{SL}_{2,l} / \Delta \langle \pm 1 \rangle$$

is a group spanned by a pair of perpendicular roots, one short and one long, and  $\text{GL}_{2,s}$  and  $\text{GL}_{2,l}$  are Levi factors of maximal parabolic subgroups of  $G_2$ . The corresponding groups  $B_\varphi$  and  $B_{\varphi'}$  are

$\text{Im}(\eta)$	$B_\varphi$	$B_{\varphi'}$
$G_2$	1	1

We leave the analysis when the connected component of the image of  $\eta$  has rank 1 or 0 to the reader to check. The group  $B_\varphi = S_3$  arises only when the image is  $\text{SO}_3 \subset \text{SL}_3 \subset G_2$ . In this case  $V = 2\mathbb{C}^3 \oplus \mathbb{C}$  where  $\mathbb{C}^3$  is the standard representation of  $\text{SO}_3$ . In particular, it is an orthogonal representation of  $W$  of determinant 1. Hence,  $B_{\varphi'} = \mu_2$ , and the map  $S_3 \rightarrow \mu_2$  is the sign character.

If  $\varphi$  is a parameter for  $G$  and  $\varphi' = f \circ \varphi$ , by Proposition 1.10 we have a surjective map

$$f_\varphi: B_\varphi \rightarrow B_{\varphi'} \cong \mu_2^k. \tag{1.10}$$

If  $\chi'$  is an irreducible representation of  $B_{\varphi'}$  (i.e. a quadratic character), we obtain a quadratic character

$$\chi = \chi' \circ f_\varphi \quad \text{of } B_\varphi. \tag{1.11}$$

We can now state the conjecture on the restriction of  $\Pi$ .

**CONJECTURE 1.13.** *Let  $\Pi$  be the minimal representation of  $H(\mathbb{Q}_p)$ . The representation*

$$\pi \otimes \pi' = \pi(\varphi, \chi) \otimes \pi'(\varphi', \chi)$$

*of  $G(\mathbb{Q}_p) \times G'(\mathbb{Q}_p)$  is a quotient of  $\Pi$  if and only if*

$$\begin{aligned}\varphi' &= f \circ \varphi, \\ \chi &= \chi' \circ f_\varphi.\end{aligned}$$

*In this case  $\text{Hom}_{G \times G'}(\Pi, \pi \otimes \pi')$  has dimension 1.*

## 2. Some consequences

Let  $\pi$  be an irreducible representation of  $G(\mathbb{Q}_p)$  and  $\pi'$  an irreducible representation of  $G'(\mathbb{Q}_p)$ . Define

$$\Theta(\pi) \tag{2.1}$$

to be the set of equivalence classes of irreducible representations  $\sigma'$  of  $G'(\mathbb{Q}_p)$  such that  $\pi \otimes \sigma'$  is a quotient of  $\Pi$ . Similarly, define

$$\Theta(\pi') \tag{2.2}$$

to be the set of equivalence classes of irreducible representations  $\sigma$  of  $G(\mathbb{Q}_p)$  such that  $\sigma \otimes \pi'$  is a quotient of  $\Pi$ . The conjecture 1.14 implies

**CONJECTURE 2.3.**

- (1) *Card  $\Theta(\pi) \leq 1$ , with equality if the character  $\chi$  of  $B_\varphi$  is quadratic.*
- (2) *Card  $\Theta(\pi') \leq 1$ , with equality if the parameter  $\varphi'$  has image in the subgroup  $G_2(\mathbb{C})$  of  $\text{Spin}_7(\mathbb{C})$ .*

We write

$$\pi \leftrightarrow \pi' \tag{2.3}$$

and say that  $\pi$  corresponds to  $\pi'$  if

$$\Theta(\pi(\varphi)) = \{\pi(\varphi')\} \quad \text{and} \quad \Theta(\pi(\varphi)) = \{\pi(\varphi')\}. \tag{2.4}$$

In particular,  $\pi \otimes \pi'$  is a quotient of  $\Pi$ .

Recall that for each semi-simple conjugacy class  $s$  in  $G_2(\mathbb{C})$ , there is an unramified representation  $\pi(s)$  of  $G(\mathbb{Q}_p)$  with Satake parameter  $s$ . Similarly, if  $s'$  is a semi-simple conjugacy class in  $\text{Spin}_7(\mathbb{C})$ , there is an unramified representation  $\pi(s')$  of  $G'(\mathbb{Q}_p)$  with Satake parameter  $s'$ .

CONJECTURE 2.5.

- (1) If  $s' = f(s)$ , then  $\pi(s) \leftrightarrow \pi(s')$ . In particular, the trivial representation  $1$  of  $G$  corresponds to the trivial representation  $1'$  of  $G'$ .
- (2)  $\text{Card } \Theta(\pi(s')) = 0$  unless  $s' = f(s)$  for some  $s$ .
- (3) The Steinberg representation  $St$  of  $G$  corresponds to the Steinberg representation  $St'$  of  $G'$ .

These predictions follow immediately from Conjecture 1.13. For (1) we note that the parameter of  $\pi(s)$  is a homomorphism  $\varphi: W' \rightarrow \hat{G}(\mathbb{C})$  with  $N = 0$ ,  $\varphi$  trivial on the inertia subgroup and  $\varphi(\text{Frob}_p) = s$ . This has  $B_\varphi = 1$ , so  $\chi = 1$ . It follows that  $\varphi'$  is the parameter of  $\pi(s')$ .

The Satake parameter of the trivial representation is  $\check{\rho}(p)$  where  $\check{\rho}$  is the co-character given by half the sum of positive co-roots. Since the image of the principal  $\text{SL}_2$  in  $G_2$  under the map  $f: G_2 \rightarrow \text{Spin}_7$  is the principal  $\text{SL}_2$  in  $\text{Spin}_7$ , we have  $f \circ \check{\rho} = \check{\rho}'$ . Hence the trivial representation  $1$  of  $G$  should correspond to the trivial representation  $1'$  of  $G'$ . The same argument shows that the Steinberg representations should correspond, as those parameters factor through the principal  $\text{SL}_2$ .

The part (1) is true for tempered representations (recall that the representation  $\pi(s)$  is tempered if  $s$  lies in a maximal compact subgroup). This is shown in [MS]. In the next section we show that  $1 \leftrightarrow 1'$ , and we verify (2). We also obtain a partial verification of (3). For example, we show that  $\Theta(St') \subseteq \{St\}$ .

3. Some calculations

We first prove a statement slightly stronger than Conj. 2.5 (2):

**PROPOSITION 3.1.** *Let  $\pi(s')$  be an unramified representation of  $G'(\mathbb{Q}_p)$ . If  $\pi(s')$  is a quotient of  $\Pi$ , then  $s' = f(s)$  for some  $s$  in  $G_2(\mathbb{C})$ .*

We note that every unramified representation  $\pi'$  can be realized as a submodule

$$\pi' \subseteq \text{Ind}_{\bar{Q}}^{G'} \bar{\sigma} \tag{3.2}$$

for some unramified representation  $\bar{\sigma}$  of  $\text{GL}_3$ . Here  $\bar{Q} = L\bar{U}$ ,  $L \cong \text{GL}_3$ , is the maximal parabolic subgroup of  $G'$ , opposite to  $Q$ , defined in (3.20), Chapter II. Let

$$\bar{s} = |p| \begin{pmatrix} z_1 & 0 & 0 \\ 0 & z_2 & 0 \\ 0 & 0 & z_3 \end{pmatrix} \text{ in } \hat{\text{GL}}_3(\mathbb{C}) = \text{GL}_3(\mathbb{C}) \tag{3.3}$$

be the Satake parameter of  $\bar{\sigma}$ . Here  $|\cdot|$  is a norm on  $\mathbb{Q}_p$ , such that  $|p| = 1/p$ . The factor  $|p|$  enters through the normalization of the parabolic induction. The corresponding modular function  $\rho_{\bar{U}}$  of  $\text{GL}_3$  is

$$\rho_{\bar{U}} = |\det|. \tag{3.4}$$

So if  $\pi'$  is contained in  $\text{Ind}_Q^{G'} \bar{\sigma}$ , then the Satake parameter of  $\pi'$  is

$$s' = \bar{s}|p|^{-1} \quad \text{in } \text{GL}_3(\mathbb{C}) \subset \text{Spin}_7(\mathbb{C}). \quad (3.5)$$

The 8-dimensional spin representation of  $\text{Spin}_7$  restricts to  $\text{GL}_3(\mathbb{C})$  as

$$\det \oplus \mathbb{C}^3 \oplus (\mathbb{C}^3)^* \oplus (\det)^*, \quad (3.6)$$

where  $\mathbb{C}^3$  is the standard representation of  $\text{GL}_3(\mathbb{C})$ , and  $*$  denotes dual representations. Hence the parameter  $s'$  fixes a vector in the spin representation (so  $s' = f(s)$  for some  $s$  in  $G_2(\mathbb{C})$ ) if

$$z_1 z_2 z_3 = 1 \quad \text{or} \quad z_i = 1 \quad \text{for some } i. \quad (3.7)$$

By Frobenius reciprocity,

$$\text{Hom}_{G'}(\Pi, \text{Ind}_Q^{G'} \bar{\sigma}) = \text{Hom}_{\text{GL}_3}(\Pi_{\bar{U}}, \bar{\sigma}), \quad (3.8)$$

so it suffices to determine which representations of  $\text{GL}_3$  appear as a quotient of  $\Pi_{\bar{U}}$ , the maximal  $\bar{U}$ -invariant quotient of  $\Pi$ .

To describe  $\Pi_{\bar{U}}$  we need some notation. Let  $Q_1$  and  $Q_2$  be the two non-conjugated maximal parabolic subgroups of  $\text{GL}_3$  intersecting in the group of lower triangular  $3 \times 3$  matrices, with Levi factors  $\text{GL}_1 \times \text{GL}_2$  and  $\text{GL}_2 \times \text{GL}_1$  respectively. Then

$$\rho'_1(g_1, g_2) = |g_1|^{-1} |\det g_2|^{1/2} \quad \text{and} \quad \rho'_2(g_2, g_1) = |\det g_2|^{-1/2} |g_1| \quad (3.9)$$

are their modular characters.

Maximal parabolic subgroups of  $G(\mathbb{Q}_p)$  can be defined as stabilizers of non-trivial nil subalgebras of  $\mathbb{O}_p = \mathbb{O} \otimes \mathbb{Q}_p$ . A nil subalgebra is a subspace of  $\mathbb{O}_p$  consisting of traceless elements with trivial multiplication (i.e. the product of any two elements is 0). The possible dimensions are 1 and 2. Fix  $V_1 \subset V_2$ , a pair of nil-subalgebras. Then  $P_1$  and  $P_2$ , the stabilizers of  $V_1$  and  $V_2$ , are two non-conjugated maximal parabolic subgroups of  $G$ , with  $P_1 \cap P_2$  a Borel subgroup. In particular,  $P_r$  has a quotient  $\text{GL}_r = \text{GL}(V_r)$ . For  $P_2$ , this quotient is isomorphic to the Levi factor. The Levi factor of  $P_1$  is isomorphic to  $\text{GL}_2 = \text{GL}(V_3/V_1)$ , where

$$V_3 = \{x \in \mathbb{O} \mid \bar{x} = -x, \quad \text{and} \quad xV_1 = 0\}. \quad (3.10)$$

The action of  $\text{GL}_2$ , the Levi factor of  $P_1$ , on  $V_1$  is given by  $\det$ . The respective modular characters are

$$\rho_1 = |\det|^{5/2} \quad \text{and} \quad \rho_2 = |\det|^{3/2}. \quad (3.11)$$

We fix the above identifications, in particular,  $P_r \times Q_r$ ,  $r = 1, 2$ , has a quotient isomorphic to

$$\mathrm{GL}_r \times \mathrm{GL}_r. \tag{3.12}$$

**PROPOSITION 3.13.** [MS; Thm. 5.3] *The  $G \times \mathrm{GL}_3$ -module  $\Pi_{\bar{U}}$  has a filtration*

$$0 = V_0 \subset V_1 \subset V_2 \subset V_3 = \Pi_{\bar{U}},$$

such that

- (1)  $V_1/V_0 \cong \mathrm{ind}_{P_2 \times Q_2}^{G \times \mathrm{GL}_3}(C_c^\infty(\mathrm{GL}_2)) \otimes |\det|^2$ .
- (2)  $V_2/V_1 \cong \mathrm{ind}_{P_1 \times Q_1}^{G \times \mathrm{GL}_3}(C_c^\infty(\mathrm{GL}_1)) \otimes |\det|^2$ .
- (3)  $V_3/V_2 = \Pi_{\bar{N}} \cong \Pi(M) \otimes |\det| \oplus 1 \otimes |\det|^2$ .

Here  $C_c^\infty(\mathrm{GL}_i)$  denotes the space of locally constant, compactly supported functions on  $\mathrm{GL}_r$ ,  $r = 1, 2$ . In both cases,  $P_r \times Q_r$  acts through the quotient isomorphic to  $\mathrm{GL}_r \times \mathrm{GL}_r$ . In (3),  $\Pi(M)$  is the minimal representation of  $M$  (the center of  $M$ , which coincides with the center of  $\mathrm{GL}_3$ , acts trivially on  $\Pi(M)$ ).

**COROLLARY 3.14.** *The possible Satake parameters of unramified  $\mathrm{GL}_3$ -quotients of  $V_i/V_{i-1}$  are:*

- (1)  $|p|(z_1, z_2, 1)$  if  $i = 1$ .
- (2)  $|p|(z_1, |p|, 1)$  if  $i = 2$ .
- (3)  $|p|(z_1, z_2, z_3)$  with  $z_1 z_2 z_3 = 1$ , or  $|p|(|p|^2, |p|, 1)$  if  $i = 3$ . The latter is the parameter of  $|\det|^2$ .

Proposition 3.1 follows from Corollary 3.14.

Let  $\pi$  be an irreducible representation of  $G$  and  $\pi'$  an irreducible representation of  $G'$ . We now explain how Proposition 3.13 can be used to obtain an upper bound on  $\Theta(\pi')$  and a lower bound on  $\Theta(\pi)$ .

Assume that  $\pi'$  is a submodule of  $\mathrm{Ind}_{\bar{Q}}^{G'}(\bar{\sigma})$ , where  $\bar{\sigma}$  is a representation of  $\mathrm{GL}_3$ . If  $\sigma$  is in  $\Theta(\pi')$ , then by the Frobenius reciprocity

$$\mathrm{Hom}_{G \times G'}(\Pi, \sigma \otimes \mathrm{Ind}_{\bar{Q}}^{G'}(\bar{\sigma})) \cong \mathrm{Hom}_{G \times \mathrm{GL}_3}(\Pi_{\bar{U}}, \sigma \otimes \bar{\sigma}), \tag{3.13}$$

$\sigma \otimes \bar{\sigma}$  is a quotient of  $\Pi_{\bar{U}}$ . Hence, if we can determine all representations  $\sigma$  of  $G$  such that  $\sigma \otimes \bar{\sigma}$  is a quotient of  $\Pi_{\bar{U}}$ , then we have an upper bound on  $\Theta(\pi')$ . Conversely, if  $\pi \otimes \bar{\sigma}$  is a quotient of  $\Pi_{\bar{U}}$ , for some  $\bar{\sigma}$ , then  $\Theta(\pi)$  is not empty, for it contains a subquotient of  $\mathrm{Ind}_{\bar{Q}}^{G'}(\bar{\sigma})$  by (3.13).

To illustrate this principle, we prove

**PROPOSITION 3.16.**  $1 \leftrightarrow 1'$

*Proof.* We first prove the following lemma.

LEMMA 3.17.

- (1)  $\Theta(1)$  is not empty.
- (2)  $\Theta(1') \subseteq \{1\}$ .

*Proof.* By Proposition 3.13,  $1 \otimes |\det|^2$  is a quotient of  $\Pi_{\bar{U}}$ . Hence by (3.15)  $\Theta(1)$  is not empty. On the other hand

$$1' \subset \text{Ind}_Q^{G'} \bar{1},$$

where  $\bar{1}$  is the trivial representation of  $\text{GL}_3$ . Its Satake parameter is

$$\begin{pmatrix} |p|^{-1} & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & |p| \end{pmatrix} = |p| \begin{pmatrix} |p|^{-2} & 0 & 0 \\ 0 & |p|^{-1} & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

Comparing with Corollary 3.14, we see that  $\sigma \otimes \bar{1}$  can be only a quotient of

$$V_1/V_0 = \text{ind}_{P_2 \times Q_2}^{G \times \text{GL}_3}(C_c^\infty(\text{GL}_2)) \otimes |\det|^2.$$

Since  $C_c^\infty(\text{GL}_2)$  is the regular representation of  $\text{GL}_2$ ,  $\sigma \otimes |\det|^{-2}$  is a quotient of

$$\text{Ind}_{P_2}^G(\tau) \otimes \text{Ind}_{Q_2}^{GL_3}(\tau^*),$$

for some irreducible representation  $\tau$  of  $\text{GL}_2$ . This implies that  $\tau^* = |\det|^{-3}$ . Hence  $\tau = |\det|^3 = \rho_2^2$ . Since 1 is unique quotient of

$$\text{Ind}_{P_2}^G(\rho_2^2),$$

it follows that  $\sigma \cong 1$ . The lemma is proved.

Let  $\bar{U}_2$  be the unipotent radical of  $\bar{P}_2$ , the maximal parabolic of  $G$ , opposite to  $P_2$ . Since  $\Pi_{\bar{U}_2}$  is given by [MS; Thm. 7.6], we can prove a statement complementary to Lemma 3.17.

LEMMA 3.18.

- (1)  $\Theta(1')$  is not empty.
- (2)  $\Theta(1) \subseteq \{1'\}$ .

The two lemmas combined imply the proposition.

We finish this section with a discussion on Steinberg representations.

PROPOSITION 3.19.  $\Theta(\text{St}') \subseteq \{\text{St}\}$ .

*Proof.* The representation  $\text{St}'$  is unique submodule of

$$\text{Ind}_Q^{G'}(\bar{\text{St}} \otimes |\det|^2),$$

where  $\bar{St}$  is the Steinberg representation of  $GL_3$ . Again, if  $\sigma \otimes St'$  is a quotient of  $\Pi$ , then by (3.15)  $\sigma \otimes (\bar{St} \otimes |\det|^2)$  is a quotient of  $\Pi_{\bar{U}}$ . However, it can not be a quotient of  $V_3/V_2$ , because the central character of  $(\bar{St} \otimes |\det|^2)$  is  $|\cdot|^6$ , and the central character of  $\Pi_M \otimes |\det|^2$  is  $|\cdot|^3$ . Also, it can not be a quotient of  $V_2/V_1$ , because the Steinberg representation is generic. Hence  $\sigma \otimes (\bar{St} \otimes |\det|^2)$  must be a quotient of  $V_1/V_0$ . So as in the proof of Lemma 3.17,  $\sigma \otimes \bar{St}$  must be a quotient of

$$\text{Ind}_{P_2}^G(\tau) \otimes \text{Ind}_{Q_2}^{GL_3}(\tau^*),$$

for an irreducible representation  $\tau$  of  $GL_2$ . It follows that  $\tau^*$  is the Steinberg representation of  $GL_2$ . Hence  $\tau$  is also the Steinberg representation. Since  $St$  is unique quotient of

$$\text{Ind}_{P_2}^G(\tau),$$

the proposition follows.

Again, in the same fashion using  $\Pi_{\bar{U}_2}$ , we can prove that if  $\pi'$  is a *unitarizable*  $\Theta$ -lift of  $St$  then

$$\pi' \cong St'. \tag{3.20}$$

As we shall see in the next chapter, the  $\Theta$ -lift of a form in  $A(St_S)$ , ( $S$  not empty) will be cuspidal, hence all its local components must be unitarizable. So (3.20) implies that the lift is Steinberg at all places in  $S$ .

### 5. Global correspondences

Let  $H$  be the adjoint group of type  $E_7$ , defined and of rank three over  $\mathbb{Q}$ . Kim [Ki] has constructed a square-integrable modular form on the exceptional hermitian domain which gives an automorphic realization

$$\theta: \otimes_p \Pi_p \rightarrow L^2(H(\mathbb{Q}) \backslash H(\mathbb{A})) \tag{0.1}$$

where  $\Pi_p$  is the minimal representation of  $H(\mathbb{Q}_p)$ , and  $\Pi_\infty$  is the space of  $K$ -finite vectors in the irreducible unitary representation  $\hat{\Pi}$  of  $H(\mathbb{R})$ , studied in Chapter 3.

In view of the local results, it is of great interest to study the lift of automorphic forms from  $G$  to  $G'$  via the kernel constructed by Kim. Let  $\theta = \theta(\otimes_p f_p)$  for some  $\otimes_p f_p \in \otimes_p \Pi_p$ . Let  $\pi$  be an automorphic representation of  $G = \text{Aut}(\mathbb{O})$ . Let  $\alpha$  be a form in  $\pi$ . Define  $\beta$ , a holomorphic form on  $G'$  by

$$\beta(g') = \int_{G(\mathbb{Q}) \backslash G(\mathbb{A})} \theta(gg')\alpha(g) dg. \tag{0.2}$$

The integral converges, because we are integrating two smooth functions over a compact set.

Let  $\pi'$  be a cuspidal automorphic representation of  $G'$ . We say that  $\pi'$  is a  $\Theta$  lift of  $\pi$  if

$$\int_{G'(\mathbb{Q}) \backslash G'(\mathbb{A})} \alpha'(g') \beta(g') dg' \quad (0.3)$$

is not zero for some  $\alpha$  and  $\alpha'$  in  $\pi'$ . The integral (0.3) converges because  $\alpha'$  is rapidly decreasing at cusps, and  $\beta$  is of moderate growth. Hence (0.2) and (0.3) define a linear functional on

$$\Pi \otimes \pi \otimes \pi'. \quad (0.4)$$

If this functional is not trivial, then local components of  $\pi$  and  $\pi'$  are related by the local correspondences studied in Chapters 3 and 4.

The existence of  $\pi'$  depends on the affirmative answer to these two questions:

- (1) Under which conditions is the form  $\beta$  cuspidal?
- (2) Under which conditions is the form  $\beta$  nonzero?

To answer these questions we study the Fourier expansion of  $\beta$  along the unipotent radical  $U$  of the Siegel parabolic subgroup of  $G' = PGSp_6$ . Note that the Fourier coefficients are parametrized by ternary quadratic forms. The holomorphic form  $\beta$  is cuspidal, if the Fourier coefficients corresponding to degenerate forms are zero [An; pg. 78]. We show that  $\beta$  is cuspidal if a local component of  $\pi$  is generic, i.e. it admits a nonzero Whittaker functional. For example, if  $\pi$  corresponds to a modular form in  $A(\varepsilon_p)$ , (5.3) in Chapter 1, then the local component at the place  $p$  has a nonzero Whittaker functional. This gives a fairly satisfactory answer to (1). On the other hand,  $L(\mathbb{Q})$ -conjugacy classes ( $L$  is the Levi factor of the Siegel parabolic) of non-degenerate Fourier coefficients are parametrized by quaternion algebras. Let  $D$  be a quaternion subalgebra of  $\mathbb{O}$  (the class of Fourier coefficients is zero if  $D \otimes \mathbb{R}$  is not definite). Let  $C$  be the centralizer in  $G$  of  $D$ . It is isomorphic to the group of norm one elements in  $D$ . Then we show that the Fourier coefficient of  $\beta$  in the conjugacy class parametrized by  $D$  is nonzero if and only if the integral of the form  $\alpha$  over  $C$  is nonzero.

This result has a striking similarity to the following well known classical result [Shn] and [Wa]: Let  $PD^\times$  be the automorphism group of  $D$ . Then one has a dual pair

$$PD^\times \times \mathrm{SL}_2 \subset \mathrm{Sp}_6$$

and one can use the Weil representation of  $\tilde{\mathrm{Sp}}_6$  to lift automorphic forms from  $PD^\times$  to  $\tilde{\mathrm{SL}}_2$ . The conjugacy classes of non-degenerate Fourier coefficients on  $\tilde{\mathrm{SL}}_2$  are parametrized by quadratic algebras. Let  $K$  be a quadratic subalgebra of  $D$ . Fix an automorphic form on  $PD^\times$ . The Fourier coefficients (the conjugacy class parametrized by  $K$ ) of the lift are nonzero if and only if the integral of the form over

the centralizer in  $PD^\times$  of  $K$  is nonzero. Again, the class of Fourier coefficients is zero if  $K$  can not be embedded into  $D$ .

We finish this chapter by showing that the two modular forms for  $G$  constructed in Chapter I lift non-trivially to  $G'$ .

1. *Kim's form*

In this section we recall few results from [Ki]. Let  $\mathbb{O}_\infty = \mathbb{O} \otimes \mathbb{R}$  and let  $J_{\mathbb{O}_\infty}^+$  be the cone of positive definite matrices in  $J_{\mathbb{O}_\infty}$ . The exceptional symmetric domain  $\mathcal{D}^+$  is the set

$$\mathcal{D}^+ = \{Z = X + iY \mid X \text{ in } J_{\mathbb{O}_\infty} \text{ and } Y \text{ in } J_{\mathbb{O}_\infty}^+\}. \tag{1.1}$$

The group of holomorphic transformation of  $\mathcal{D}^+$  is isomorphic to  $H_{sc}(\mathbb{R})/\langle \pm 1 \rangle$ , the connected component of  $H(\mathbb{R})$ .

Let  $f_\infty^0$  be a nonzero vector in the one-dimensional minimal  $K$ -type in  $\Pi_\infty^+$ , and let  $f_p^0$  ( $p$  is a finite prime) be the spherical vector in  $\Pi_p$ . Kim has constructed a modular form  $F$  on  $\mathcal{D}^+$  of weight 4 and level 0, which corresponds to  $\theta(\otimes_p f_p^0)$ . Moreover, he has obtained a Fourier series decomposition

$$F(Z) = 1 + 240 \sum_{T \in J_{\mathcal{R}}} a_T e^{2\pi i \text{Tr}(T \circ Z)}, \tag{1.2}$$

where  $J_{\mathcal{R}}$  is the set of  $A$  in  $J_{\mathbb{O}}$  with entries in  $\mathcal{R}$ . A coefficient  $a_T$  is zero unless the rank of  $T$  is 1, and it is in the closure of the cone  $J_{\mathbb{O}_\infty}^+$ . In this case

$$a_T = \sum_{d|c(T)} d^3, \tag{1.3}$$

where  $c(T)$  is the largest integer such that  $c(T)^{-1}T$  is in  $J_{\mathcal{R}}$ . In particular,  $a_T > 0$ .

2. *Local theory*

In this section all objects are over  $\mathbb{Q}_p$ . As in Chapter 2, Section 3, let  $P = MN$  be the maximal parabolic subgroup of  $H$  such that  $M$  is the group of isogenies of the determinant form on the exceptional Jordan algebra  $J_{\mathbb{O}_p}$ , and  $N \cong J_{\mathbb{O}_p}$  as an  $M$ -module. Let  $\lambda$  be the isogeny character of  $M$  defined by (3.5) in Chapter 2.

Let  $\psi$  be a non-trivial character of  $\mathbb{Q}_p$ . Let  $A$  be an element in  $J_{\mathbb{O}_p}$ . Define a character  $\psi_A$  of  $N$  by

$$\psi_A(B) = \psi(\text{Tr}(A \circ B)), \tag{2.1}$$

where  $B \in J_{\mathbb{O}_p} \cong N$ . A nonzero element  $A$  in  $J_{\mathbb{O}_p}$  has rank 1 if

$$A^2 = \text{Tr}(A)A. \tag{2.2}$$

Let  $\Omega$  be the set of elements of rank 1. We will need the following result [MS; Thm. 1.1].

**PROPOSITION 2.3.** *The minimal representation  $\Pi$  of  $H$  fits into the sequence of  $P$ -modules*

$$C_c^\infty(\Omega) \subset \Pi \subset C^\infty(\Omega),$$

where  $C^\infty(\Omega)$  denotes the space of locally constant functions on  $\Omega$  and  $C_c^\infty(\Omega)$  is the subspace of compactly supported functions. Moreover

(1) if  $f \in C^\infty(\Omega)$ , then

$$\begin{cases} \Pi(n)f(X) = \psi_X(n)f(X), & n \in N \cong J_{\mathbb{O}_p} \\ \Pi(m)f(X) = |\lambda(m)|^2 f(\tilde{m}(X)), & m \in M, \end{cases}$$

where  $\tilde{m}(X)$  is defined by

$$\mathrm{Tr}(\tilde{m}(X) \circ Y) = \mathrm{Tr}(X \circ m(Y)),$$

for all  $Y$  in  $J_{\mathbb{O}_p}$ .

(2)  $\Pi/C_c^\infty(\Omega) = \Pi_N$ ,

where  $\Pi_N$  is the maximal  $N$ -invariant quotient of  $\Pi$ .

Let  $(\pi, E)$  be a smooth  $N$ -module. Define  $E_{N, \psi_A}$  to be the quotient of  $E$  by the subspace  $E(N, \psi_A)$  spanned by the elements  $\{\pi(n)v - \psi_A(n)v \mid n \in N, v \in E\}$ . Since the functor  $E \rightsquigarrow E_{N, \psi_A}$  is exact [BZ], Proposition 2.3 implies the following.

**COROLLARY 2.4.** *Let  $A$  be a non-zero element in  $J_{\mathbb{O}}$ . Then*

$$\dim \Pi_{N, \psi_A} \leq 1.$$

*It is 1 if and only if the rank of  $A$  is 1. In this case, the dual of  $\Pi_{N, \psi_A}$  is spanned by ‘evaluation at  $A$ ’.*

### 3. Fourier coefficients

Fix  $\psi$ , a non-trivial character of  $\mathbb{A}/\mathbb{Q}$ , with conductor  $\prod_p \mathbb{Z}_p$ . Let  $A \in J_{\mathbb{Q}}$ . As in the previous section we define a character  $\psi_A$  of  $N(\mathbb{A})$ .

For a function  $\theta = \theta(\otimes_p f_p)$ , define the Fourier coefficient  $\theta_A$  by

$$\theta_A(g) = \int_{N(\mathbb{Q}) \backslash N(\mathbb{A})} \theta(ng) \psi_A(n) \, dn. \quad (3.1)$$

Corollary 2.3 implies that  $\theta_A(g) = 0$  if  $A$  has rank  $> 1$ .

We consider the Fourier expansion of  $\beta$  defined by (0.2) along  $U$ , the unipotent radical of the Siegel parabolic of  $G'$ . We identify  $U(\mathbb{Q})$  with the set of  $3 \times 3$  symmetric matrices with coefficients in  $\mathbb{Q}$ . Let  $B$  be an element in  $U(\mathbb{Q})$ . Then

$$\beta_B(1) = \int_{U(\mathbb{Q}) \backslash U(\mathbb{A})} \int_{G(\mathbb{Q}) \backslash G(\mathbb{A})} \theta(ug) \alpha(g) \psi_B(u) \, dg \, du. \quad (3.2)$$

Write  $\theta(g) = \sum_{rk A \leq 1} \theta_A(g)$  and substitute into the formula for  $\beta_B(1)$ . Then

$$\beta_B(1) = \int_{G(\mathbb{Q}) \backslash G(\mathbb{A})} \sum_{\psi_A|_{U(\mathbb{A})} = \psi_B^{-1}} \theta_A(g) \alpha(g) dg. \tag{3.3}$$

**LEMMA 3.4.** *The group  $G(\mathbb{Q})$  acts transitively on the set of all rank-one elements  $A$  in  $J_{\mathbb{Q}} \cong N(\mathbb{Q})$  such that*

$$\psi_A|_{U(\mathbb{A})} = \psi_B^{-1}.$$

*Proof.* After conjugating  $B$  with an element in  $L(\mathbb{Q}) \cong \text{GL}_3(\mathbb{Q})$ , we can assume that  $B$  is given by a diagonal matrix:

$$B = \begin{pmatrix} a & 0 & 0 \\ 0 & b & 0 \\ 0 & 0 & c \end{pmatrix}.$$

Let

$$A = \begin{pmatrix} d & \bar{z} & y \\ z & e & \bar{x} \\ \bar{y} & x & f \end{pmatrix},$$

such that  $\psi_A|_U = \psi_B^{-1}$ . Then

$$\begin{aligned} d &= -a, & e &= -b, & f &= -c, \\ \bar{x} &= -x, & \bar{y} &= -y, & \bar{z} &= -z. \end{aligned}$$

Since  $A$  is rank-one, we have  $A^2 = \text{Tr}(A)A$  and this implies

$$\begin{aligned} x^2 &= -bc, & y^2 &= -ca, & z^2 &= -ab, \\ yz &= -ax, & zx &= -by, & xy &= -cz. \end{aligned}$$

We have four cases:

- (1)  $a = b = c = 0$ . Then  $x^2 = y^2 = z^2 = 0$ . Since  $\mathbb{O}$  is a division algebra, this implies that  $x = y = z = 0$ . Hence  $A = 0$  is the only possibility.
- (2)  $a \neq 0, b = c = 0$ . Then again  $x^2 = y^2 = z^2 = 0$ , and  $A = -B$  is the only possibility.

- (3)  $ab \neq 0$  but  $c = 0$ . Then  $x^2 = y^2 = 0$ . Therefore  $x = y = 0$ . Since  $z^2 = -ab$ ,  $K = \mathbb{Q}(z)$  is a quadratic subalgebra of  $\mathbb{O}$ . By a theorem of Jacobson [J3],  $G(\mathbb{Q})$  acts transitively on the set of traceless  $z$  such that  $z^2 = -ab$ . The stabilizer of a point is isomorphic to  $SU(K^\perp) = SU_3^K$ . This form of  $SL_3$  is compact over  $\mathbb{R}$ , quasi-split for all finite primes, and split by  $K$ .
- (4)  $abc \neq 0$ . In this case  $x, y$  and  $z$  are standard generators of a quaternion subalgebra  $D$  of  $\mathbb{O}$ . By a theorem of Jacobson [J3],  $G(\mathbb{Q})$  acts transitively on the set of triples  $(x, y, z)$ . The stabilizer of a point is isomorphic to the group of norm one elements in  $D$ .

Finally, note that  $A$  will exist only if  $B$  is a semi-definite matrix. The lemma is proved.

Assume that  $B = 0$ . The lemma implies that

$$\beta_0(1) = \int_{G(\mathbb{Q}) \backslash G(\mathbb{A})} \theta_0(g) \alpha(g) dg. \quad (3.5)$$

Since  $\theta_0(1) = \theta_0(m)$  for any  $m \in [M(\mathbb{A}), M(\mathbb{A})]$  (the Fourier coefficient  $a_0$  is constant in the Kim's formula), and  $G(\mathbb{A}) \subset [M(\mathbb{A}), M(\mathbb{A})]$ ,

$$\beta_0(1) = \theta_0(1) \int_{G(\mathbb{Q}) \backslash G(\mathbb{A})} \alpha(g) dg. \quad (3.6)$$

*Remark.* Ginzburg, Rallis, and Soudry have constructed in [GRS1] an automorphic representation of the split group  $E_{7,7}(\mathbb{A})$ , whose local components are the minimal representations. Moreover, they have shown that the constant term along the unipotent radical of the  $E_{6,6}$ -maximal parabolic is a sum of two automorphic representations of  $[M(\mathbb{A}), M(\mathbb{A})] = E_{6,6}(\mathbb{A})$ : the trivial representation, and a representation whose local components are the minimal representations. In the case of  $E_{7,3}(\mathbb{A})$ , the latter summand can not appear, because the local component  $E_{6,2}(\mathbb{R})$  of  $[M(\mathbb{A}), M(\mathbb{A})]$  has no minimal representation.

Now assume that  $B \neq 0$ . Fix  $A'$ , a representative of the orbit. Since  $A'$  and  $nA'$  ( $n \in \mathbb{Z}$ ) are in the same  $L(\mathbb{Q})$ -orbit, we shall assume that the entries of  $A'$  lie in  $\mathcal{R}$ , the maximal order of  $\mathbb{O}$ . Let  $\mathcal{A}$  be the composition algebra generated by the entries of  $A'$ . Let

$$C(\mathbb{Q}) = C_{G(\mathbb{Q})}(\mathcal{A}). \quad (3.7)$$

Then

$$\beta_B(1) = \int_{C(\mathbb{Q}) \backslash G(\mathbb{A})} \theta_{A'}(g) \alpha(g) dg. \quad (3.8)$$

Recall that  $\theta = \theta(\otimes_p f_p)$  and we fix  $f_\infty$ . The map

$$\theta \mapsto \theta_{A'}(1) \quad (3.9)$$

defines a linear functional on  $\mathbb{C}f_\infty \otimes (\otimes_{p \neq \infty} \Pi_p)$  which by the local uniqueness (Corollary 2.3) must be a product of local functionals, i.e. evaluations at  $A'$ . Therefore, there exists a nonzero constant  $c$  such that

$$\theta_{A'}(1) = c \prod_{p \neq \infty} f_p(A'). \tag{3.10}$$

We have to say a word or two about the above ‘infinite’ product. Let  $f_p^0 \in \Pi_p$  be the spherical vector. Note that  $f_p^0(A') \neq 0$ . This follows from the Kim’s formula, which says that  $\theta_{A'}(1) \neq 0$  if  $f_p = f_p^0$  for all  $p$ , and the coefficients of  $A'$  are in  $\mathcal{R}$ . We normalize  $f_p^0$  so that  $f_p^0(A') = 1$ , hence the above product is always just a finite product.

Let  $g = g_\infty g_f$  be an element in  $G(\mathbb{A})$ , where  $g_\infty$  is in  $G(\mathbb{R})$  and  $g_f$  in  $G(\hat{\mathbb{Q}})$ . Arguing as before

$$\theta_{A'}(g) = c(g_\infty) \prod_{p \neq \infty} f_p(g_p^{-1}(A')), \tag{3.11}$$

where  $c(g_\infty)$  is a constant depending on  $g_\infty$ . It follows that  $\theta_{A'}(g)$  is  $C(\hat{\mathbb{Q}})$ -left invariant. Since it is also  $C(\mathbb{Q})$ -invariant, and  $C(\mathbb{Q})C(\hat{\mathbb{Q}})$  is dense in  $C(\mathbb{A})$  by the weak approximation [Kn], it follows that  $\theta_{A'}(g)$  is  $C(\mathbb{A})$ -left invariant. Hence, from (3.8)

$$\beta_B(1) = \int_{C(\mathbb{A}) \backslash G(\mathbb{A})} \theta_{A'}(g) P_\alpha^C(g) dg, \tag{3.12}$$

where

$$P_\alpha^C(g) = \int_{C(\mathbb{Q}) \backslash C(\mathbb{A})} \alpha(vg) dv. \tag{3.13}$$

#### 4. Non-vanishing and cuspidality

We first give a criterion for non-vanishing of non-degenerate Fourier coefficients. Every  $3 \times 3$  symmetric is  $L(\mathbb{Q})$ -conjugated to a diagonal matrix. Let

$$B = \begin{pmatrix} a & 0 & 0 \\ 0 & b & 0 \\ 0 & 0 & c \end{pmatrix} \text{ in } U(\mathbb{Q}) \tag{4.1}$$

be of rank three, i.e.  $abc \neq 0$ . Let  $D$  be a quaternion algebra spanned by 1 and traceless  $x, y$ , and  $z$ , subject to the following relations

$$\begin{aligned} x^2 &= -bc, & y^2 &= -ca, & z^2 &= -ab \\ yz &= -ax, & zx &= -by, & xy &= -cz. \end{aligned} \tag{4.2}$$

Replacing  $B$  with another diagonal matrix in the same conjugacy class amounts to rescaling and permuting the generators  $x, y$  and  $z$ . In particular, generic  $L(\mathbb{Q})$ -orbits are parametrized by quaternion algebras.

Henceforth, we assume that  $D$  is contained in  $\mathbb{O}$  (this is possible iff  $B$  is a definite matrix). In particular,  $x, y$  and  $z$  are traceless octonions. Then

$$A' = - \begin{pmatrix} a & z & \bar{y} \\ \bar{z} & b & x \\ y & \bar{x} & c \end{pmatrix} \quad (4.3)$$

is a rank one matrix in  $J_{\mathbb{O}}$  such that  $\psi_{A'}|_U = \psi_B^{-1}$ . Again, there is no harm in assuming that the entries of  $A'$  are in  $\mathcal{R}$ , the maximal order in  $\mathbb{O}$ .

Let  $\pi$  be an automorphic representation of  $G$ . Fix a form  $\alpha$  in  $\pi$ . Let  $S$  be a set of finite places such that if  $p \notin S$ , then

$$\begin{cases} \alpha \text{ is } G(\mathbb{Z}_p)\text{-invariant,} \\ D_p \text{ is the algebra of } 2 \times 2 \text{ matrices,} \\ a, b, c \text{ are not divisible by } p. \end{cases} \quad (4.4)$$

**PROPOSITION 4.5.** *Let  $C$  be the centralizer of  $D$  in  $G$ . Then the following are equivalent:*

- (1)  $P_{\alpha}^C \neq 0$ , and
- (2)  $\beta_B(1) \neq 0$  for a choice of  $\theta = \theta(\otimes_p f_p)$ , with  $f_p = f_p^0$  for all  $p \notin S$ .

*In particular, if  $P_{\alpha}^C \neq 0$ , then  $\beta$  is unramified for all  $p \notin S$ .*

*Proof.* Obviously, if  $P_{\alpha}^C = 0$  then  $\beta_B(1) = 0$  for any choice of  $\theta$ , by (3.12). Assume that  $P_{\alpha}^C \neq 0$ , and let  $\theta^0 = \theta(\otimes_p f_p)$ , such that

- (1)  $f_{\infty} = f_{\infty}^0$ , a vector in the minimal ‘ $K$ -type’ of  $\Pi_{\infty}^+$ .
- (2) If  $p \notin S$ , then  $f_p = f_p^0$  ( $H(\mathbb{Z}_p)$ -invariant vector).

**LEMMA 4.6.** *Let  $\mathbb{Q}_S = \prod_{p \in S} \mathbb{Q}_p$ . If  $g \in G(\mathbb{A})$ , we write  $g = g_{\infty} g_S g^S$  where  $g_{\infty} \in G(\mathbb{R})$ ,  $g_S \in G(\mathbb{Q}_S)$  and  $g^S \in \prod_{p \notin S} G(\mathbb{Q}_p)$ . Then there exists a nonzero constant  $c$ , such that for every  $g \in G(\mathbb{A})$*

$$\theta_{A'}^0(g) = c f_S(g_S^{-1}(A')) \prod_{p \notin S} \chi_p(g_p),$$

where  $f_S = \otimes_{p \in S} f_p$ , and  $\chi_p$  is the characteristic function of  $C(\mathbb{Z}_p) \backslash G(\mathbb{Z}_p)$  where  $C(\mathbb{Z}_p) = C(\mathbb{Q}_p) \cap G(\mathbb{Z}_p)$ . Note that, since  $D_p$  is split,  $C(\mathbb{Q}_p)$  is isomorphic to  $\mathrm{SL}_2(\mathbb{Q}_p)$ .

*Proof.* By (3.11) we have

$$\theta_{A'}^0(g) = c \prod_{p \neq \infty} f_p(g_p^{-1}(A')).$$

In this case, however, the constant  $c$  does not depend on  $g_\infty$  because  $f_\infty^0$  is  $G(\mathbb{R})$ -invariant.

Let  $g_p \in G(\mathbb{Q}_p)$  such that  $f_p^0(g_p^{-1}(A')) \neq 0$ . Let  $x', y', z'$  be the off-diagonal terms of  $g_p^{-1}A'$ . Since  $f_p^0$  is  $N(\mathbb{Z}_p)$ -invariant, it follows from Proposition 2.3 (1) that  $f_p^0$  is supported in  $J_{\mathcal{R}_p} = J_{\mathcal{R}} \otimes \mathbb{Z}_p$ , hence  $x', y', z' \in \mathcal{R}_p$ .

Consider  $\mathcal{R}/p\mathcal{R}$ , the octonion algebra over  $\mathbb{Z}/p\mathbb{Z}$ . The projections of  $(x, y, z)$ , the off-diagonal terms of  $A'$ , and  $(x', y', z')$  onto  $\mathcal{R}/p\mathcal{R}$  are  $G(p)$ -conjugated by the theorem of Jacobson. It follows from Hensel's lemma that  $(x, y, z)$  and  $(x', y', z')$  are  $G(\mathbb{Z}_p)$ -conjugated. Therefore, the function

$$g_p \mapsto f_p^0(g_p^{-1}(A'))$$

is supported in  $C(\mathbb{Z}_p) \backslash G(\mathbb{Z}_p) \subset C(\mathbb{Q}_p) \backslash G(\mathbb{Q}_p)$ . Since  $f_p^0$  is  $G(\mathbb{Z}_p)$ -invariant,

$$f_p^0(g_p^{-1}(A')) = f_p^0(A') = 1$$

for  $g_p$  in  $G(\mathbb{Z}_p)$ . The lemma follows.

Let  $Y$  be a finite collection of elements  $n_i$  in  $N(\mathbb{R})$ , together with a collection of numbers  $c_i$ . Define

$$\theta^Y(g) = \sum_i c_i \theta^0(g n_i).$$

Obviously

$$\theta_{A'}^Y(g) = \sum_i c_i \psi_{A'}(g_\infty n_i g_\infty^{-1}) \theta_{A'}^0(g_\infty).$$

Furthermore, recall that  $\psi_x(y) = \psi(\text{Tr}(x \circ y)) = \psi_y(x)$ , so

$$\theta_{A'}^Y(g) = \sum_i c_i \psi_{n_i}(g_\infty^{-1}(A')) \theta_{A'}^0(g_\infty),$$

and

$$\theta_{A'}^Y(g) = c \sum_i c_i \psi_{n_i}(g_\infty^{-1}(A')) f_S(g_S^{-1}(A')) \prod_{p \notin S} \chi_p(p)$$

by Lemma 4.6.

In general,  $\theta^Y$  is not a ‘K-finite’ vector. Still, it is a smooth function on  $H(\mathbb{Q})\backslash H(\mathbb{A})$ , and we can use it to define a function  $\beta$  on  $G'$  using the formula (0.2). By (3.12)

$$\beta_B(1) = \int_{C(\mathbb{A})\backslash G(\mathbb{A})} \theta_{A'}^Y(g) P_\alpha^C(g) dg.$$

Substituting the expression for  $\theta_{A'}^Y$ , and using that  $P_\alpha^C$  is  $G(\mathbb{Z}_p)$ -invariant for every  $p \notin S$ ,

$$\begin{aligned} \beta_B(1) &= c \int_{C(\mathbb{R} \times \mathbb{Q}_S)\backslash G(\mathbb{R} \times \mathbb{Q}_S)} \sum_i c_i \psi_{n_i}(g_\infty^{-1}(A')) f_S \\ &\quad (g_S^{-1}(A')) P_\alpha(g_\infty g_S) dg_\infty dg_S \prod_{p \notin S} \mu_p, \end{aligned}$$

where

$$\mu_p = \int_{\text{SL}_2(\mathbb{Q}_p)\backslash G_2(\mathbb{Q}_p)} \chi_p dg_p = \frac{\#G_2(p)}{\#\text{SL}_2(p)p^{11}} = (1 - p^{-6}).$$

The infinite product is  $\zeta_S^{-1}(6)$ , and therefore nonzero. Let  $p$  be a prime in  $S$ . By Proposition 2.3,  $f_p$  can be any compactly supported, locally constant function on the set of rank one matrices in  $J_{\mathbb{Q}_p}$ , hence the integral over  $C(\mathbb{Q}_S)\backslash G(\mathbb{Q}_S)$  will be nonzero for a suitable choice of  $f_S$ . Since  $S(\mathbb{R})\backslash G(\mathbb{R})$ , the  $G(\mathbb{R})$ -orbit of  $A'$ , is compact, by the Stone–Weierstrass theorem  $\{\sum_i c_i \psi_{n_i}\}$  is a dense family of continuous functions. Hence the integral over  $C(\mathbb{R})\backslash G(\mathbb{R})$  can be arranged to be non-zero, too.

Since

$$\theta^Y = \sum_{n \in \mathbb{Z}} \theta_n^Y$$

in locally uniform convergence of smooth functions on  $H(\mathbb{Q})\backslash H(\mathbb{A})$  where  $\theta_n^Y$  belongs to the  $n$ -th ‘K-type’ of  $\Pi_\infty$ , at least one of these summands has to produce a nonzero  $\beta$ , with a non-trivial Fourier coefficient at  $B$ . The proposition is proved.

Next, let

$$B = \begin{pmatrix} a & 0 & 0 \\ 0 & b & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \text{in } U(\mathbb{Q}) \tag{4.7}$$

be of rank two, i.e.  $ab \neq 0$ . Let  $K = \mathbb{Q}(z)$  be a quaternion subalgebra of  $\mathbb{O}$ , such that  $z$  is traceless and  $z^2 = -ab$ .

**PROPOSITION 4.8.** *Let  $C$  be the centralizer of  $K$  in  $G$ . Then the following are equivalent:*

- (1)  $P_\alpha^C \neq 0$ , and
- (2)  $\beta_B(1) \neq 0$  for a choice of  $\theta$ .

*Proof.* Analogous to the proof of Proposition 4.5. One also needs non-vanishing of a special value of the zeta-function  $\zeta_\chi$ , where  $\chi$  is the character of  $\mathbb{A}^\times$  corresponding to  $K$  via class-field theory. This is provided in [EG].

**COROLLARY 4.9** *Let  $\pi = \hat{\otimes}_v \pi_v \subset L^2(G(\mathbb{Q}) \backslash G(\mathbb{A}))$  be an irreducible automorphic representation. Assume that:*

- (1)  $\pi_\infty \cong W(k_1, k_2) \otimes \mathbb{C}$ , with  $k_2 \neq 0$ , or there exists a finite prime  $p$  such that  $\pi_p$  has a Whittaker functional.
- (2) There exists  $\alpha \in \pi$  and  $D$ , a quaternion subalgebra of  $\mathbb{O}$ , such that  $P_\alpha^C \neq 0$ .

*Then  $\Theta(\pi)$  contains a non-trivial cusp form on  $G'$ , unramified at all places  $p \notin S$ , where  $S$  is given by (4.4).*

*Proof.* The second condition and Proposition 4.5 imply that  $\beta$  is non-zero, and unramified outside  $S$ .

To show cuspidality we need to show that  $\beta_B = 0$  for any  $B$  of rank less than or equal to 2. Assume that the rank is 0 or 1. The first condition implies that the  $\pi$  is not isomorphic to the trivial form on  $G$ . Hence the period over  $G$  is 0. This implies that  $\beta_B$  is also 0, by (3.6) and (3.12).

To show vanishing for  $B$  of rank 2, we have to show that  $SU_3$ -periods vanish, by Proposition 4.8. Assume not. Then each local component of  $\pi$  has a non-trivial  $SU_3$ -invariant functional. This means that  $\pi_\infty$  has an  $SU_3(\mathbb{R})$ -fixed vector, and by the Frobenius reciprocity,  $(\pi_p)^*$ , the contragredient of  $\pi_p$ , is a quotient of  $C_c^\infty(G(\mathbb{Q}_p)/SU_3^K(\mathbb{Q}_p))$ . By the branching law  $G_2 \downarrow A_2$  [Sa2], the representation  $W(k_1, k_2)$  has an  $SU_3(\mathbb{R})$ -fixed vector iff  $k_2 = 0$ . Also, a generic  $p$ -adic representation can not be a quotient of  $C_c^\infty(G(\mathbb{Q}_p)/SU_3^K(\mathbb{Q}_p))$ , in view of the following.

**LEMMA 4.10.** *Let  $F$  be a  $p$ -adic field, and  $K \subset \mathbb{O} \otimes F$  a quadratic subalgebra. Let  $SU(K^\perp) = SU_3^K$  be the centralizer of  $K$  in  $G = \text{Aut}(\mathbb{O} \otimes F)$ . Then the  $G$ -module*

$$C_c^\infty(G/SU_3^K)$$

*does not have a Whittaker functional.*

*Proof.* Let  $B \subset G$  be a Borel subgroup. The space  $C_c^\infty(G/SU_3^K)$  has a  $B$ -invariant filtration with successive quotients  $C_c^\infty(\mathcal{O})$ , where  $\mathcal{O}$  runs over the finite set of  $B$ -orbits on  $G/SU_3^K$ . We need to show that each of the subquotients does not have a Whittaker functional, so our task is to compute  $B$ -orbits on  $G/SU_3^K$ , or equivalently,  $SU_3^K$ -orbits on  $G/B$ .

Let  $M_2(F)$  be the algebra of  $2 \times 2$ -matrices over  $F$ , with involution

$$\overline{\begin{pmatrix} a & b \\ c & d \end{pmatrix}} = \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}.$$

Then  $\mathbb{O} \otimes F$  is isomorphic to the algebra  $M_2(F) \oplus M_2(F)$  with multiplication

$$(a, b)(a', b') = (aa' + \bar{b}'b, b'a + b\bar{a}').$$

Using this realization of  $\mathbb{O} \otimes F$ , it is easy to compute  $\mathrm{SU}_3^K$ -orbits on  $G/B$ . Assume, for example, that  $K \cong F \oplus F$ , the subalgebra of diagonal matrices in  $M_2(F)$ . Then  $\mathrm{SU}_3^K = \mathrm{SL}_3(F)$ . Let  $V$  be the space of traceless elements in  $\mathbb{O} \otimes F$ , then

$$V = V_3 \oplus V_3^* \oplus K^0,$$

under the action of  $\mathrm{SL}_3(F)$ . Here  $V_3$  is the standard representation of  $\mathrm{SL}_3(F)$ , and  $K^0 = K \cap V$ . The set  $G/B$  can be identified with partial flags

$$V_1 \subset V_2 \subset V$$

consisting of 1 and 2-dimensional spaces with trivial octonion multiplication. We note that  $V_2$  is always contained in the 3-dimensional space

$$V_1\Delta = \{x \in V \mid x \cdot V_1 = 0\}.$$

We have three different cases.

- (1) The group  $\mathrm{SL}_3(F)$  acts transitively on partial flags  $V_1 \subset V_2$  such that  $V_1 \subset V_3$ . Indeed,  $\mathrm{SL}_3(F)$  acts transitively on lines in  $V_3$ , and the stabilizer of a line  $V_1$  is a maximal parabolic subgroup. Its Levi factor  $\mathrm{GL}_2(F)$  acts transitively on the 2-dimensional space

$$V_1\Delta/V_1.$$

By the same argument,  $\mathrm{SL}_3(F)$  acts transitively on partial flags such that  $V_1 \subset V_3^*$ .

- (2) The group  $\mathrm{SL}_3(F)$  acts with two orbits on partial flags  $V_1 \subset V_2$  such that  $V_1 \subset V_3 \oplus V_3^*$ , but not contained in  $V_3$  or  $V_3^*$ . Indeed, in this case

$$V_1 = F(x + y) \subset V_3 \oplus V_3^*,$$

where  $x^2 = xy = y^2 = 0$ , and we have two orbits, depending whether

$$V_2 = Fx + Fy = V_1\Delta \cap (V_3 \oplus V_3^*)$$

or not.

- (3) The group  $\mathrm{SL}_3(F)$  acts transitively on partial flags  $V_1 \subset V_2$  such that  $V_1$  is not contained in  $V_3 \oplus V_3^*$ . Indeed,  $\mathrm{SL}_3(F)$  acts transitively on such  $V_1$ , and the stabilizer is  $\mathrm{SL}_2(F)$ , which acts transitively on the 2-dimensional space

$$V_1\Delta/V_1.$$

Next, let  $B$  be a Borel subgroup fixing a partial flag  $V_1 \subset V_2$ . Its short simple root group acts by  $x \mapsto x + b$  on  $V_2/V_1$  and its long simple root group by  $x \mapsto x + b$

on  $V_1\Delta/V_2$ . Now, it is a simple matter to check that in each case  $B' = B \cap \text{SL}_3(F)$  will contain 1-dimensional subgroup acting by  $x \mapsto x + b$  on  $V_2/V_1$  or  $V_1\Delta/V_2$ . Hence,  $C_c^\infty(B/B')$  does not have a Whittaker functional, and this implies the lemma.

5. Examples

We prove the non-vanishing of the  $\Theta$ -lifts of the automorphic representations  $\pi$  constructed in Proposition 7.7 and Proposition 7.12 of Chapter 1.

Let  $D$  be a definite quaternion algebra over  $\mathbb{Q}$ . Then the  $\mathbb{Q}$  algebra  $D \oplus Dv$  with multiplication

$$(a + bv)(a' + b'v) = (aa' - \bar{b}'b) + (b'a + b\bar{a}')v \tag{5.1}$$

is a definite octonion algebra, hence it is isomorphic to the Cayley's octonion algebra  $\mathbb{O}$ . Thus  $D$  embeds in  $\mathbb{O} = D \oplus D^\perp$ , and if we fix an element  $v$  in  $D^\perp$  with  $v^2 = -1$ , we get an isomorphism of the subgroup  $C$  of  $G = \text{Aut}(\mathbb{O})$  fixing  $D$  with  $D_{\mathbb{N}=1}^\times$ , the group of norm-one elements in  $D$

$$d(a + bv) = a + (db)v, \quad d\bar{d} = 1. \tag{5.2}$$

The subgroup  $\text{SO}_4(D) = \{(d, d') \in D^\times \times D^\times \mid \text{Nd} = \text{Nd}'\} / \Delta\mathbb{Q}^\times$  of  $G$  acts on  $\mathbb{O}$  as follows

$$(d, d')(a + bv) = d's(d')^{-1} + (db(d')^{-1})v. \tag{5.3}$$

In particular, it stabilizes  $D \subset \mathbb{O}$ , and contains  $C$  as the subgroup  $\{(d, 1)\}$ . The group  $\text{SO}_4(D)$  is the centralizer in  $G$  of the involution  $i(a + bv) = a - bv$  of  $\mathbb{O}$ .

Now suppose  $D$  is the algebra of Hamilton's quaternions, ramified at 2 and  $\infty$ . We will show the following.

**PROPOSITION 5.4.** *There is an embedding of  $D$  into  $\mathbb{O}$  such that*

$$C(\mathbb{A}) = C(\mathbb{Q}) \times C(\mathbb{R}) \times (C(\hat{\mathbb{Q}}) \cap K(2)),$$

where  $K(2)$  is the subgroup of elements in  $G(\hat{\mathbb{Z}})$  congruent to 1 mod 2.

*Proof.* First some facts about Hamilton quaternions, independent of octonions. It has the maximal order  $R$  defined by Hurwitz

$$R = \mathbb{Z}i \oplus \mathbb{Z}j \oplus \mathbb{Z}k \oplus \mathbb{Z} \left( \frac{1 + i + j + k}{2} \right),$$

with unit group

$$R^\times = \left\langle \pm 1, \pm i, \pm j, \pm k, \frac{\pm 1 \pm i \pm j \pm k}{2} \right\rangle$$

of order 24. This order gives a model for  $C$  over  $\mathbb{Z}$ , with  $C(\mathbb{Z}) = R^\times$  and bad reduction at 2. For  $p$  odd,  $C(\mathbb{Z}_p)$  is isomorphic to  $\mathrm{SL}_2(\mathbb{Z}_p)$ .

For  $p = 2$ , let  $R_2 = R \otimes \mathbb{Z}_2$  be a maximal order in  $D_2 = D \otimes \mathbb{Z}_2$ . Then

$$C(\mathbb{Z}_2) = (R_2^\times)_{\mathbb{N}=1} = C(\mathbb{Q}_2) = (D_2^\times)_{\mathbb{N}=1}.$$

The element  $\varpi = (1 + i)$  is a uniformizing element in  $R_2$ , and we have a filtration by normal subgroups:

$$(R_2^\times)_{\mathbb{N}=1} \supset_3 (1 + \varpi R_2)_{\mathbb{N}=1} \supset_{(2,2)} (1 + \varpi^2 R_2)_{\mathbb{N}=1} \supset_2 (1 + \varpi^3 R_2)_{\mathbb{N}=1} \supset_{(2,2)} \cdots,$$

where  $\supset_{(2,2)}$ , for example, denotes that the quotient is isomorphic to the Klein four-group.

We have

$$R^\times \cap (1 + \varpi R_2)_{\mathbb{N}=1} = \langle \pm 1, \pm i, \pm j, \pm k \rangle,$$

$$R^\times \cap (1 + \varpi^2 R_2)_{\mathbb{N}=1} = \langle \pm 1 \rangle,$$

$$R^\times \cap (1 + \varpi^3 R_2)_{\mathbb{N}=1} = 1.$$

Since the global units lie in distinct cosets of  $(R_2^\times)_{\mathbb{N}=1}/(1 + \varpi^3 R_2)_{\mathbb{N}=1}$ , and the latter group has order 24, we obtain a direct product decomposition

$$C(\mathbb{Z}_2) = R^\times \times (1 + \varpi^3 R_2)_{\mathbb{N}=1}.$$

The mass formula (of Eichler) gives

$$C(\mathbb{A}) = C(\mathbb{Q})(C(\mathbb{R}) \times C(\hat{\mathbb{Z}})),$$

with intersection  $C(\mathbb{Z})$ . Hence we have a direct product

$$C(\mathbb{A}) = C(\mathbb{Q}) \times \left( C(\mathbb{R}) \times (1 + \varpi^3 R_2)_{\mathbb{N}=1} \times \prod_{p \neq 2} C(\mathbb{Z}_p) \right).$$

To finish the proof of the proposition, we need to find an embedding of  $D$  in  $\mathbb{O}$  such that

$$C(\hat{\mathbb{Q}}) \cap K(2) = (1 + \varpi^3 R_2)_{\mathbb{N}=1} \times \prod_{p \neq 2} C(\mathbb{Z}_p).$$

Let  $\mathcal{R}$  be the ring of integral octonions constructed by Coxeter, so  $K(2)$  is the subgroup of  $\mathrm{Aut}(\mathcal{R} \otimes \hat{\mathbb{Z}})$  which acts trivially on  $\mathcal{R}/2\mathcal{R}$ . We embed the Hurwitz  $R$  into the Coxeter  $\mathcal{R}$  via  $i \mapsto e_1, j \mapsto e_2, k \mapsto e_4$ . If we take  $v = e_3$  then

$$\mathbb{O} = D \oplus D^\perp \quad \text{and} \quad \mathcal{R} \supset_{(2,2)} R \oplus R^\perp$$

The general element of  $\mathcal{R}$  has the form

$$\frac{1}{2}(a + be_3),$$

with  $a, b$  in  $\varpi R$ ,  $\varpi = (1 + i) = (1 + e_1)$ . If we write

$$a = \varpi\alpha,$$

$$b = \varpi\beta,$$

then for the above to lie in  $\mathbb{O}$ , we need the congruence

$$\alpha \equiv \bar{\beta} \pmod{\varpi R}.$$

It is now a simple matter to check that  $(1 + \varpi R_2)_{\mathbb{N}=1} \times \prod_{p \neq 2} C(\mathbb{Z}_p)$  is the subgroup of  $G(\hat{\mathbb{Z}})$  fixing  $D$ . Similarly,  $(1 + \varpi^3 R_2)_{\mathbb{N}=1} \times \prod_{p \neq 2} C(\mathbb{Z}_p)$  is the subgroup fixing  $D$  and acting trivially on  $\mathcal{R}/2\mathcal{R}$ . The proposition is proved.

**PROPOSITION 5.5.** *Let  $\pi$  be the automorphic representation of  $G$  given in Proposition 7.7 in Chapter I. ( $\pi_\infty$  is isomorphic to the irreducible 64-dimensional representation of  $G(\mathbb{R})$  of highest weight  $\rho$ ,  $\pi_2$  is the Steinberg representation of  $G(\mathbb{Q}_2)$  and  $\pi_p$  is unramified for all  $p \neq 2$ ). Then  $\pi$  lifts to a cusp form  $\pi'$  on  $G'$ , with:*

- (1)  $\pi'_\infty$  is a holomorphic discrete series representation with infinitesimal character  $(6, 4, 2)$ .
- (2)  $\pi'_p$ , for  $p \neq 2$  is unramified with Satake parameter in  $G_2(\mathbb{C}) \subset \text{Spin}_7(\mathbb{C})$ .
- (3)  $\pi'_2$  is the Steinberg representation.

*Proof.* We will show that the period over  $C$  given by Proposition 5.4 is non-zero for a  $K(2)$ -fixed function in  $\pi$ . Using the direct product decomposition

$$G(\mathbb{Q}) \backslash G(\mathbb{A}) = G(\mathbb{R}) \times K(2),$$

one identifies the space of  $K(2)$ -fixed vectors in  $\pi$  with the space of matrix coefficients of  $W$  on  $G(\mathbb{R})$ . By Proposition 5.4 we have to show that there exists a matrix coefficient of  $W$  such that its integral over  $C(\mathbb{R})$  is not zero.

Every finite-dimensional representation of  $G(\mathbb{R})$  has a  $C(\mathbb{R}) \cong \text{SU}_2(\mathbb{R})$ -fixed vector. Indeed, we have a chain of groups

$$\text{SU}_2 \subset \text{SU}_3 \subset G,$$

where  $\text{SU}_3$  is the stabilizer in  $G$  of a quadratic subalgebra of  $D$ , for example  $\mathbb{Q}(i)$ . Since it is true that every representation of  $\text{SU}_3(\mathbb{R})$  has  $\text{SU}_2(\mathbb{R})$ -fixed vectors, the same is true for  $G(\mathbb{R})$ .

Let  $w$  be a  $C(\mathbb{R})$ -fixed vector in  $W$ . Obviously, the matrix coefficient  $\langle w, gw \rangle$  has non-vanishing integral over  $C(\mathbb{R})$ . Hence the Fourier coefficient at

$$B = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

is not zero. The proposition follows from Corollary 4.9. The information about the local components of  $\pi'$  follows from Corollary 3.9 of Chapter 3 and Proposition 3.1 of Chapter 4.

We now assume that  $D$  is the definite quaternion algebra ramified at 5 and  $\infty$ .

**PROPOSITION 5.6.** *There is an embedding of  $D$  into  $\mathbb{O}$  and a Borel subgroup  $B(5) \subset G(5)$  such that*

$$C(\mathbb{A}) = C(\mathbb{Q}) \times C(\mathbb{R}) \times (C(\hat{\mathbb{Q}}) \cap K_0(5)),$$

where  $K_0(5)$  is the subgroup of elements in  $G(\hat{\mathbb{Z}})$  reducing to  $B(5) \pmod{2}$ .

*Proof.* Let  $R$  be a maximal order in  $D$ , which is unique up to  $D^\times$ -conjugacy. We have  $R^\times = \mu_6$ . The order  $R$  gives a model of  $C$  over  $\mathbb{Z}$ , with bad reduction at 5. The units lie in the 6 distinct cosets for the subgroup  $(1 + \varpi R)$ , where  $\text{Tr}(\varpi) = 0$  and  $\mathbb{N}(\varpi) = 5$ . Hence we obtain a direct product

$$C(\mathbb{A}) = C(\mathbb{Q}) \times \left( C(\mathbb{R}) \times (1 + \varpi R_5)_{\mathbb{N}=1} \times \prod_{p \neq 5} C(\mathbb{Z}_p) \right).$$

Let  $\mathcal{R}$  be the Coxeter's order in  $\mathbb{O}$ . There is an embedding  $R \rightarrow \mathcal{R}$ , which is unique up to conjugacy by  $\text{Aut}(\mathcal{R}) = G(\mathbb{Z})$ . Let  $R^\perp$  be the orthogonal complement of  $R$  in  $\mathcal{R}$ ; again we find that

$$R \oplus R^\perp \subset_{(5,5)} \mathcal{R}$$

and that the subgroup of  $G(\hat{\mathbb{Z}})$  fixing  $R \otimes \hat{\mathbb{Z}}$  is precisely  $(1 + \varpi R_5)_{\mathbb{N}=1} \times \prod_{p \neq 5} C(\mathbb{Z}_p)$ .

Since  $(1 + \varpi R_5)_{\mathbb{N}=1}$  is a 5-group, its reduction in  $G(5)$  is contained in the unipotent radical of some Borel subgroup  $B(5)$ . Therefore  $C(\hat{\mathbb{Q}}) \cap K_0(5) = (1 + \varpi R_5)_{\mathbb{N}=1} \times \prod_{p \neq 5} C(\mathbb{Z}_p)$ , which completes the proof.

In Section 7 of Chapter 1, we showed that the space

$$\mathcal{S} = G(\mathbb{Q}) \backslash G(\mathbb{A}) / G(\mathbb{R}) \times K_0(5) \tag{5.7}$$

had 7 elements. We also showed that there was a nonzero function  $f: \mathcal{S} \rightarrow \mathbb{Q}$ , unique up to scaling, in the Steinberg subspace:  $T_i f = -f$  for the three generators  $T_0, T_1, T_2$  of the Iwahori–Hecke algebra at 5.

The function  $f$  determines a 1-dimensional subspace  $\langle F \rangle$  in the automorphic representation  $\pi$  of Proposition 7.12. The period of  $F$  over  $C(\mathbb{Q}) \backslash C(\mathbb{A})$  is nonzero if and only if  $f(e) \neq 0$ , where  $e$  is the identity double coset of  $\mathcal{S}$  ( $e$  is the image of  $C(\mathbb{A})$ , by the Proposition 5.6). A computer calculation, performed by D. Pollack and J. Lansky, showed that  $f(e) \neq 0$ . Hence we obtain

**PROPOSITION 5.8.** *Let  $\pi$  be the automorphic representation of  $G$  given in Proposition 7.12 in Chapter 1. ( $\pi_\infty \cong 1$ ,  $\pi_5$  is the Steinberg representation of  $G(\mathbb{Q}_5)$  and  $\pi_p$  is unramified for all  $p \neq 5$ ). Then  $\pi$  lifts to a cusp form  $\pi'$  on  $G'$ , with*

- (1)  $\pi'_\infty$  is a holomorphic discrete series representation with infinitesimal character  $(3, 2, 1)$ .
- (2)  $\pi'_p$ , for  $p \neq 5$  is unramified with Satake parameter in  $G_2(\mathbb{C}) \subset \text{Spin}_7(\mathbb{C})$ .
- (3)  $\pi'_5$  is the Steinberg representation.

The automorphic representation  $\pi'$  corresponds to a classical holomorphic form of weight 4 and level 5.

### 6. Periods

As we indicated in the introduction, the complement of the motive  $M$  in  $M'$  should be given by the classes of Hilbert modular 3-folds. If so, the forms on  $G'$  coming from  $G$  should be characterized as those having non-zero periods over the cycles given by the Hilbert modular 3-folds. We give an affirmative answer to this question in the local setting.

#### 1. A see-saw dual pair in $E_n$

We let  $F$  be a  $p$ -adic field,  $E$  a separable cubic extension of  $F$ , and  $H$  a split adjoint group over  $F$  of type  $E_6, E_7$  or  $E_8$ . Let  $H' = H \rtimes \Gamma$  be the semi-direct product of  $H$  with its group of outer automorphisms  $\Gamma$ . Note that  $\Gamma \cong \mathbb{Z}/2\mathbb{Z}$  for  $E_6$ , and is trivial otherwise. The see-saw pair in  $H'$  is

where all groups are quasi-split over  $F$ ,  $D_4^E$  is a twist of the simply connected group of type  $D_4$  by  $\text{Gal}(F/F) \rightarrow S_3$ , the group of outer automorphisms of  $D_4$ , and the subgroups  $G'$  and  $C'_E$  are tabulated below.

Type of $H$	$G'$	$C'_E$	
$E_6$	$\text{PGL}_3 \rtimes \Gamma$	$(R_{E/F} \mathbb{G}_m / \mathbb{G}_m) \rtimes \Gamma$	(1.2)
$E_7$	$\text{PGSp}_6$	$R_{E/F} \text{SL}_2 / \mu_2$	
$E_8$	$F_4$	$D_4^E$ .	

The center of  $G'$  is trivial, and the pair  $G_2 \times G'$  is a maximal subgroup of  $H'$ , whereas the center of  $C'_E$  is

$$K_4^E = (R_{E/F}\mu_2)/\mu_2 = D_4^E \cap C'_E, \tag{1.3}$$

a twist of the Klein group  $K_4$ , and the subgroup  $D_4^E \times C'_E/\Delta K_4^E$  is not maximal, for it is contained in the centralizer in  $H'$  of any non-trivial element of  $K_4^E$ .

In the following section, we will characterize the irreducible representations  $\pi'$  of  $G'(F)$  which appear as quotients of the minimal representation of  $H'(F)$ ; these are the representations with a nonzero,  $C'_E$ -invariant linear functional, for some  $E$ .

Let  $\text{Tr}: E \rightarrow F$  be the trace form. Since  $E$  is separable, the pairing  $E \times E \rightarrow F$  given by  $(v, w) = \text{Tr}(vw)$  is non-degenerate. Let  $\{v_1, v_2, v_3\}$  be a basis for  $E$  over  $F$ , and consider the  $F$ -linear embedding  $E \rightarrow J(F)$

$$\alpha \mapsto A_\alpha = (\text{Tr}(\alpha \cdot v_i v_j)), \tag{1.4}$$

where  $J(F)$  is the 6-dimensional space of symmetric  $3 \times 3$  matrices over  $F$ . The matrix

$$e = A_1 = (\text{Tr}(v_i v_j)) \tag{1.5}$$

has  $\det(e) \neq 0$ , by the non-degeneracy of the pairing.

Now let  $D \subseteq \mathbb{O} \otimes F$  be an  $F$ -subalgebra, on which the norm form is non-degenerate and represents 0. Let  $J(D)$  be the  $F$ -vector space of  $3 \times 3$  Hermitian symmetric matrices over  $D$ . We then have a chain of subspaces

$$Fe \subset E \subset J(F) \subset J(D) \subseteq J_0 \otimes F. \tag{1.6}$$

Let  $L'$  be the algebraic group of all invertible linear maps on  $J(D)$  which preserve the determinant form  $\det: J(D) \rightarrow F$ . These groups are tabulated below [EG]

$D$	$J(D)$	$L'$	
$F + F$	$M_3(F)$	$(\text{SL}_3 \times \text{SL}_3/\Delta\mu_3) \rtimes \Gamma$	(1.7)
$M_2(F)$	$\wedge^2 F^6$	$\text{SL}_6/\mu_2$	
$\mathbb{O} \otimes F$	$J_0 \otimes F$	$E_6$	

where we have identified  $J(D)$  with a more familiar  $L'$ -module. Note that the center of  $L'$  is  $\mu_3$ .

Let  $\mathfrak{l}$  be the Lie algebra of  $L'$ , and  $V_3$  the standard 3-dimensional representation of  $\text{SL}(3)$ . In [Sa2] it is shown that the direct sum

$$\mathfrak{h} = (\mathfrak{sl}(3) \oplus \mathfrak{l}) \oplus (V_3 \otimes J(D)) \oplus (V_3 \otimes J(D))^* \tag{1.8}$$

has the structure of a simple, split Lie algebra of type  $E_n$ , ( $n = 6, 7, 8$ ), with a  $\mathbb{Z}/3\mathbb{Z}$ -gradation given by the action of the center of the subgroup

$$\mathrm{SL}_3 \times L'/\Delta\mu_3, \tag{1.9}$$

of  $H'$ .

It can be checked that the centralizer of  $e$  in  $L' \subset H'$  is  $G'$ , and the centralizer of  $G'$  in  $H'$  has Lie algebra

$$\mathfrak{g}_2 = \mathfrak{sl}(3) \oplus (V_3 \otimes Fe) \oplus (V_3 \otimes Fe)^*, \tag{1.10}$$

of type  $G_2$ .

Let  $E_0 \subset E$  be the kernel of the trace map  $\mathrm{Tr}: E \rightarrow F$ . The centralizer of  $E \subset J(D)$  in  $L'$  is  $C'_E$ , and the centralizer of  $C'_E$  in  $H'$  has Lie algebra

$$\mathfrak{d}_4^E = (\mathfrak{sl}(3) \oplus E_0) \oplus (V_3 \otimes E) \oplus (V_3 \otimes E)^*, \tag{1.11}$$

of type  $D_4$ , split by  $E$  [Ru]. This gives a construction of the see-saw pair.

### 2. Periods

The minimal representation  $\Pi$ , defined in Chapter 4, can be easily extended to  $H'$ ; more precisely, the polarization used in [KS; pg 212] is  $\Gamma$ -invariant, and by taking the structural coefficients to be  $\Gamma$ -invariant, the representation extends to  $H'$  in an obvious way.

Consider the decomposition (1.8) of  $\mathfrak{h}$ . Let  $\mathfrak{t}$  be the Cartan subalgebra of  $\mathfrak{sl}(3)$ , consisting of diagonal traceless matrices. Let

$$h = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix} \in \mathfrak{t} \subset \mathfrak{sl}(3) \subset \mathfrak{h}. \tag{2.1}$$

Define

$$\mathfrak{h}(k) = \{x \in \mathfrak{h} \mid [h, x] = kx\}. \tag{2.2}$$

Since the eigenvalues of  $h$  on the standard 3-dimensional representation  $V_3$  of  $\mathfrak{sl}(3)$  are  $-1, 0, 1$ , the decomposition (1.8) implies that  $\mathfrak{h}(k) \neq 0$  for  $k = -2, -1, 0, 1, 2$ . For example,

$$\mathfrak{h}(0) = J(D)^* \oplus \mathfrak{t} \oplus \mathfrak{h} \oplus J(D). \tag{2.3}$$

Write  $\mathfrak{g} = \bar{\mathfrak{n}} \oplus \mathfrak{m} \oplus \mathfrak{n}$  where

$$\begin{cases} \mathfrak{m} = \mathfrak{h}(0), \\ \mathfrak{n} = \mathfrak{h}(1) \oplus \mathfrak{h}(2), \\ \bar{\mathfrak{n}} = \mathfrak{h}(-1) \oplus \mathfrak{h}(-2). \end{cases} \tag{2.4}$$

Then  $\mathfrak{p} = \mathfrak{m} \oplus \mathfrak{n}$  is a maximal parabolic subalgebra. The nilpotent radical  $\mathfrak{n}$  is a two-step nilpotent (Heisenberg) Lie algebra, with the center  $\mathfrak{z} = \mathfrak{h}(2)$ . Analogous statements are true for the opposite algebra  $\bar{\mathfrak{p}} = \mathfrak{m} \oplus \bar{\mathfrak{n}}$ . Under the action of  $\mathfrak{t} \oplus \mathfrak{l} \subset \mathfrak{m}$ , we have direct sum decompositions

$$\begin{cases} \mathfrak{n}/\mathfrak{z} \cong \mathfrak{h}(1) = F \oplus J(D) \oplus J(D)^* \oplus F^*, \\ \bar{\mathfrak{n}}/\bar{\mathfrak{z}} \cong \mathfrak{h}(-1) = F^* \oplus J(D)^* \oplus J(D) \oplus F. \end{cases} \quad (2.5)$$

Let  $P' = M'N$  be the ‘Heisenberg’ maximal parabolic subgroup of  $H'$ , with Lie algebra  $\mathfrak{p}$ . Let  $Z$  be the center of  $N$ . The quotient of  $N$  by  $Z$  is commutative and  $N/Z \cong \mathfrak{n}/\mathfrak{z}$  as  $M$ -modules. Let  $\bar{P}' = M'\bar{N}$  be the parabolic subgroup opposite to  $P'$ , and  $\bar{Z}$  be the center of  $\bar{N}$ . The Killing form on  $\mathfrak{h}$ , the Lie algebra of  $H$ , defines a non-degenerate pairing  $\langle, \rangle$  between  $N/Z$  and  $\bar{N}/\bar{Z}$ . In terms of the identifications (2.5) this pairing is

$$\langle (x, u, u^*, x^*), (y^*, v^*, v, y) \rangle = xy^* + \langle u, v^* \rangle + \langle v, u^* \rangle + yx^*. \quad (2.6)$$

Let  $\Omega$  be the smallest non-trivial  $M'$ -orbit in  $N/Z$ . It is simply the orbit of a highest weight vector.

**PROPOSITION 2.7.** ( $p \neq 2$  if  $G = E_8$ ) *Let  $\Pi$  be the minimal representation of  $H'$ . Let  $\bar{Z}$  be the center of  $\bar{N}$  as above. Let  $\Pi_{\bar{Z}}$  and  $\Pi_{\bar{N}}$  be the maximal  $\bar{Z}$ -invariant and  $\bar{N}$ -invariant quotients of  $\Pi$ . Then*

$$0 \rightarrow C_c^\infty(\Omega) \rightarrow \Pi_{\bar{Z}} \rightarrow \Pi_{\bar{N}} \rightarrow 0,$$

where  $C_c^\infty(\Omega)$  denotes the space of locally constant, compactly supported functions on  $\Omega$ . The action of  $\bar{P}'$  on  $C_c^\infty(\Omega)$  is given by

$$\Pi(\bar{n})f(x) = \psi(\langle x, \bar{n} \rangle)f(x), \quad \bar{n} \in \bar{N},$$

$$\Pi(m)f(x) = |\det(m)|^{s/d}f(m^{-1}xm), \quad m \in M',$$

where  $\psi$  is a non-trivial additive character of  $F$ ,  $\det$  is the determinant of the representation of  $M'$  on  $\bar{N}/\bar{Z}$ ,  $d$  is the dimension of  $N/Z$ . The values are given by the following table.

$G$	$s$	$d$
$E_6$	4	20
$E_7$	6	32
$E_8$	10	56

*Proof.* This is a simplified version of [MS; Thm 6.1].

We are now ready to prove the main result of this section. Let  $e$  be an element in  $J(D)$ , such that  $(e, e, e) = 6$ , and let  $G' \subset L' \subset H'$  be the centralizer of  $e$  in  $L'$ .

**PROPOSITION 2.8.** *Let  $\pi'$  be a representation of  $G'$  with a nonzero  $C'_E$ -invariant functional. Then  $(\pi')^*$  (the contragredient of  $\pi'$ ) is a quotient of  $\Pi$ .*

*Proof.* If we compare the construction (1.10) of the dual pair  $G_2 \times G'$  with the definition of  $P'$ , we find that

$$G_2 \cap P' = P_2 = \text{GL}_2 U_2$$

is the ‘Heisenberg’ parabolic of  $G_2$ . Note that  $Z \subset U_2$ , and in terms of the identification (2.5)

$$U_2/Z \cong F \oplus Fe \oplus Fe^* \oplus F^* \subset F \oplus J(D) \oplus J(D)^* \oplus F^* \cong N/Z,$$

where  $e^*$  is a  $G'$ -fixed element of  $J(D)^*$ , normalized by  $\langle e^*, e \rangle = 3$ .

The action of  $\text{GL}_2$ , the Levi factor of  $P_2$ , on  $U_2/Z$  is isomorphic to  $\text{Sym}^3(F^2) \otimes \det^{-1}$ , and this was studied in [Wr]. Generic  $\text{GL}_2$ -orbits correspond to cubic separable extensions of  $F$  as follows. A point  $(a, b, c, d)$  in  $U_2/Z$  defines a binary cubic form

$$ax^3 + bx^2y + cxy^2 + dy^3.$$

The corresponding  $\text{GL}_2$ -orbit is generic if and only if the form has three different solutions in  $\mathbb{P}(\bar{\mathbb{Q}}_p)$ . Assume that  $a = 6$ . This just means that  $(6, 0)$  is not a solution of the cubic form. Then

$$E = F[x]/(x^3 + bx^2 + cx + d)$$

is the cubic separable algebra.

The pairing  $\langle, \rangle$  restricts to a non-degenerate pairing between  $U_2/Z$  and  $\bar{U}_2/\bar{Z}$ . Therefore, the point  $(a, b, c, d)$  and the additive character  $\psi$  define a character  $\psi_E$  of  $\bar{U}_2$ .

**LEMMA 2.9.** *Let  $\Pi_{\bar{U}_2, \psi_E}$  be the maximal quotient of  $\Pi$  such that  $\bar{U}_2$  acts as the character  $\psi_E$  on it. Then*

$$\Pi_{\bar{U}_2, \psi_E} = C_c^\infty(G'/C'_E).$$

*Proof.* Proposition 2.8 and (2.6) imply that

$$\Pi_{\bar{U}_2, \psi_E} = C_c^\infty(\Omega)_{\bar{U}_2, \psi_E} = C_c^\infty(\Omega_E),$$

where

$$\Omega_E = \{(\mathfrak{b}, u, u^*, d) \in \Omega \mid \langle u, e^* \rangle = b \quad \text{and} \quad \langle e, u^* \rangle = c\}.$$

We need to show that  $G'$  acts transitively on  $\Omega_E$ . Let  $\mathfrak{q} \subset \mathfrak{m}$  be a maximal parabolic subalgebra given by

$$\mathfrak{q} = (\mathfrak{t} \oplus \mathfrak{h}) \oplus J.$$

Let  $Q'$  be the corresponding subgroup of  $M'$ , and let  $U \cong J$  be the unipotent radical of  $Q'$ . The group  $Q'$  preserves the partial flag in  $N/Z$

$$F \oplus J(D) \oplus J(D)^* \oplus F^* \supset J(D) \oplus J(D)^* \oplus F^* \supset J(D)^* \oplus F^* \supset F^*.$$

By [MS; Lem. 7.5],  $Q'$  has 4 orbits on  $\Omega$ , given by the position of a point in  $\Omega$ , relative to the flag. Hence,  $\Omega_E$  is in the  $Q'$ -orbit of  $(\mathfrak{b}, 0, 0, 0)$ . Moreover, by (2.5) the Levi factor of  $Q'$  preserves the line through  $(\mathfrak{b}, 0, 0, 0)$ , hence  $\Omega_E$  is contained in the  $U$ -orbit of  $(\mathfrak{b}, 0, 0, 0)$ .

This action of  $U$  is given by (3.11) in Chapter 2. In particular, if  $z$  is an element in  $U \cong J$ , then

$$z(\mathfrak{b}, 0, 0, 0) = (1, \mathfrak{b}z, 3z \times z, (z, z, z)).$$

So, if  $(\mathfrak{b}, u, u^*, d)$  is an element in  $\Omega_E$ , then

$$\begin{cases} u = \mathfrak{b}z, \\ u^* = 3z \times z, \\ d = (z, z, z) \end{cases}$$

and, since  $e^* = \frac{1}{2}e \times e$ ,

$$\begin{cases} b = 3(z, e, e) \\ c = 3(z, z, e) \\ d = (z, z, z). \end{cases}$$

Hence, the characteristic polynomial of  $z$  is

$$\begin{aligned} \mathfrak{b} \det(\lambda - z) &= (\lambda - z, \lambda - z, \lambda - z) \\ &= (e, e, e)\lambda^3 - 3(z, e, e)\lambda^2 + 3(z, z, e)\lambda - (z, z, z) \\ &= \mathfrak{b}\lambda^3 - b\lambda^2 + c\lambda - d. \end{aligned}$$

The group  $G'$  acts transitively on the set of such elements. In the first case,  $L'$  acts transitively on  $3 \times 3$  matrices with determinant 1, so we can assume that  $e$  is the identity matrix. Hence  $\Omega_E$  is the set of all  $3 \times 3$  matrices with the characteristic polynomial (in the usual sense)

$$6\lambda^3 - b\lambda^2 + c\lambda - d,$$

i.e. it is a regular, semi-simple conjugacy class of  $3 \times 3$  matrices. This implies the lemma in the first case. The general case can be reduced to this [J2; Thm. 10, pg 389]. The lemma is proved.

The proposition follows from Lemma 2.9 and the Frobenius reciprocity.

**COROLLARY 2.10.** *Let  $E$  be a cubic separable algebra over  $F$ . Let  $\pi(s')$  be an unramified representation of  $PGSp_6(F)$  with a non-trivial  $C'_E$ -functional. Then  $s' = f(s)$  for some semisimple conjugacy class  $s$  in  $G_2(\mathbb{C})$ . If, in addition,  $\pi(s')$  is tempered, then the converse is also true.*

*Proof.* Note that every unramified representation of  $PGSp_6$  is self-contragredient. So, if  $\pi(s')$  has a non-trivial  $C'_E$ -invariant functional,  $\pi(s')$  is a quotient of  $\Pi$  by Proposition 2.8. Hence  $s' = f(s)$  for some  $s$  in  $G_2(\mathbb{C})$  by Proposition 3.1 of Chapter 4.

Now assume that  $\pi(s')$  is tempered and  $s' = f(s)$ . Then  $\pi(s) \otimes \pi(s')$  is a quotient of  $\Pi$  by [MS; Thm. 5.4]. Since  $\pi(s)$  is a fully induced representation [Ke], it follows that  $\pi(s)_{\bar{U}_2, \psi_E} \neq 0$ . By Lemma 2.9

$$\Pi_{\bar{U}_2, \psi_E} = C_c^\infty(G'/C'_E),$$

so the second statement follows from Frobenius reciprocity.

## Acknowledgments

We would like to thank K. Magaard and J.-P. Serre for many stimulating and helpful discussions during the course of this work.

The second author was generously supported by an NSF Postdoctoral Fellowship and a Sloan Research Fellowship.
