PSYCHOLOGICAL AND PSYCHIATRIC ASPECTS OF REHABILITATION PARTICIPANTS
IN THE KARABAKH WAR

E. Mehdiyev

Psychiatry, Central Military Clinic Hospital, Baku, Azerbaijan

Most often in combat environment adaptive and disadaptive registers of prepathologic level as well as prenosologic registers of pathologic level of psychic disorders are observed in servicemen. Acute psychologic and pathologic reactions of prenosologic level are predominant, with a considerable decrease of reactive psychoses, especially of their persisting forms.

Principal peculiarity of the system of psychological correction and medicopsychological rehabilitation of combatants with combat stress reactions is, alongside with the detection and treatment of psychic disorders, its orientation to the restoration of their combat ability, if they are to participate in combat actions, and the restoration of their working ability, if they are to resume peaceful life. The author worked out approaches to the creation of a system of medicopsychologic and psychocorrective rehabilitation measures for this group of persons and suggested a number of original psychotherapeutic methods.

The realization of psychocorrective and medicopsychologic rehabilitation measures oversteps the competence limits of psychiatrists alone and can be effective if their efforts are combined with the activity of specialists in psychophysiology, social and medical psychology, narcology and some other fields.
